Yes, but it`s too involved to relate in this thread.
Cet a copy of "Radio-Electronic Transmission Fundamentals" by B.
Whitfield Griffith, Jr., Library of Congress Catalog Card Number:
61-13756. Chapter 48 is titled: "The Field of Two Antennas". It does not
disappoint.

Best regards, Richard Harrison, KB5WZI

2926. Re: Best salty ground?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-21 00:00:00 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <8qdao3$6nq$1@uranium.btinternet.com>
Source record: 180118

For all antennas, especially low verticals, the lower the ground resistivity the smaller the power lost in the ground. (Unless, of course, resistivity is so high it is becoming an insulator.)

Ground resistivity is determined mainly by its water content and by the salts disolved in the water.

Salt sea water has the lowest resistivity of 0.22 ohm-metres. It can be considered lossless when only a very few radials or a plate is immersed in it. Suppose the loss resistance is 0.1 ohms underneath a 1/4-wave vertical having a radiation resistance of 37 ohms. Radiating efficiency will be 99.73 percent.

Now dilute the salt sea water with an equal amount of marsh water such that the resistivity doubles. The loss resistance will also double and radiating efficiency will fall to 99.46 percent. But what's a difference in signal strength of 0.0117 decibels between friends. It's only about 1/500th of an S-unit.

In summary, if the water tastes salty, wherever you are you are well on the way to winning the contest. Just don't drink too much of the filthy stuff.

What CUTS?!

This is a LOOP. All you do is BEND the wire. If hams can't do this, then let me turn in my license....

Last one I did took ten minutes to make with a block so described.

Some people just make'em out of copper tubing and hang'em from their porches--with NO SUPPORTS.

Frankly, you only require one or two supports per arm.

Steve, do you REALLY understand what the heck this antenna is ABOUT?? have you LOOKED at the WEB SITE?

http://www.fractenna.com/ham/hampage1.html

How can you possibly make such silly statements if you've looked at it?

Or, like the 'squirrel run' loop you described--with 5 inch piping (!!!))--, is this ANOTHER joke?

Hi Jim,

Well, 10M is the best place to put the FQY through its paces, and 10 hasn't been open much til recently this season.. The 10M contest in December is a wonderful chance to show its stuff! Besides, it's the weekend before finals so I have it off!

Yuri and Chuck both op on 10M and can thus best attempt to beat me.

They won't!

:-)

No. I am suggesting that peer reviewers do the job they volunteered to do.
There is no' mercy' involved.

I have long benefited from peer review critiiiiiiques. Omce in a whoile you get
one that's off the wall, but what usually happens then is that person isn't
sent any more MS' to look at....

Sure! Why NOT peer review! Just recognize that a former TV repairman with no
publishing record does not a peer make--for a theoretical counter example.

Dead Sea? Salt Lake?

OK, I gather that salt water vs. salt water marsh is very close, perhaps indistinguishible. Still, I don't see any practical experiences or measurements. Next time I will go to the ocean and marsh area I will try to do some measurements and try to correlate salinity vs. depth of RF penetration. Any known and proven method of doing that? Perhaps ferrite rod antenna?

Thanks!

I am planning to build a multiband dipole like the AlpahDelta.
Is there any reason that I can not feed a
40mtr,20mtr,18,mtr,12mtr,10mtr with a single feed line?

I have a a small lot and need to have something on hf.
I also plan on installing a gap vertical by the spring.
The rig is IC 746 .

the other question could i use the same support poles for the abvoe
mentioned bands if I were to build a sky loop.
thank you

Readers be so advised:

Thomas Rauch , W8JI, is in the process of being sued for libel by me. For several months now, he has harassed me with no provocation to him.

Recently he has made a death threat to me. He has also been threatening with public statements that he will disrupt my public appearances. This coupled with his death threat has made it impossible for me to address any gatherings of radio amateurs in the future, and I have already canceled and turned down 3 appearances recently.

Keep that in mind the next time you want to hear from an authority at Dayton, for example.

I have already received 4 e-mails asking' What's wrong (one said "Dr. ASSHOLE") with Tom's comments?'.

Some radio amateurs may pretend that fractal antennas are some lunatic technology within their sole purview. In fact, the situation is quite the opposite. Over a 100 fractal -element antenna articles have ben published since I started this field in 1988. Fractal Antenna Systems, Inc., which holds the IP on the technology, is undergrowing rapid growth to keep up with demand. Finally, as we can see from a very recent example in Octber QST (KE6MWX's) stellar peformance in teh California State Science fair).

And yes; hams have built'em and use'em.

My latest tally is over 1000. There are likely many others that i don't hear about.

I have always been very helpful in answering fractal antenna questions. The fact that I do not do so HERE anymore is solely because of a few individuals, who will resort to no restraint whatsoever, even and including death threats.

It is important to realize that any and all of these individuals could have asked these questions on a moderated list--the fractal antenna reflector at

fractalantenna-subscribe@egroups.com

In fact, the fractal antenna reflector is now at its largest average subscriber size since its inception in January 1999.

I will, for the first time in 9 months, quote from a Thomas Rauch post at others' requests.

>The design system works this way. The "designer" keeps trying random
>fractal shapes and eventually hits one that sort of fits an
>application. The designer then uses a computer to refine the shape
>through a series of trial and error changes until the "form" winds up
>as good as it can get within certain guidelines.
>

This is essentially correct. And I am very proud of the work and toil I have put into this to make it work.

In fact, computers do this job now. They use a 'guided trial and error' process of optimization which works almost exactly in this way. It is called GENETIC ALGORITHM ANTENNA OPTIMIZATION. In the past few years it has become the premier means of coming up with better antenna designs.

In fact, Bob Hohlfeld and I have just put the finishing touches on fractal-coded genetic algroithm optimzation software for antennas.

But I am hardly taking credit for such optimzation approaches. They were pioneered--with a different optimzation algorithm-- by Landstorfer and Sacher, who arrived at OPTIMUM antenna shapes which we now know are RANDOM FRACTALS, and so identified in my pioneering 1995 paper on fractal antennas..

Even their book says it all:

OPTIMIZATION OF WIRE ANTENNAS published in 1985. First work reported right here in Boston in 1976!

I understand that former TV repairmen with no publishing records--who live in rural states with no easy library access, may be terribly frustrated that younger people are pulling the world out from under them--technically speaking--but that's the way its gone.

The REAL question is: what RIGHT does this former TV repairman with no publishing record HAVE to 1) harass and libel; 2) threaten my life?

Don't be diverted: I am not.

Nathan Cohen, Ph.D.

Exactly the point I was making, Chip; sending articles to ones colleagues is a normal and accepted process. I raised the issue to point out that the implication that there was something underhanded in your wish for peer review was a false one.

My choice of the word "would" in the paragraph was not intended to say that would not.

Anyone with experience with the HF2V roof mounted? How is the performance?
How about mounting and radials?

Thanks,

Steve, W2WX

Anyone who would avoid feedback on a scientific MS is a fool.

Peter 'O' (PO) Brackett wants to know who was/will review my latest SETI manuscripts before they are published.

That's easy: Frank Drake.

The last thing I would do is publish something wrong and embarassing in a proceedings in honor of him.

Watta guy!

What has been unfortunate about some of the noise, Tom, is that those who come to this forum as readers to learn more about antennas will learn things wrong by reading the noise.

I can tell that there are some who don't like Chip, but expressing that dislike by some of the incorrect things I have seen said about his antenna design does more than get his goat -- it confuses the newcomer who really is trying to understand antennas.

I don't always succeed, but I try my darndest to keep my personal feelings about someone and my technical discussions separate. And if we want to discuss our personal feelings, rec.radio.amateur.antenna is not the newsgroup chartered for that sort of thing. :-)

Just a bit of explanation about my posting style. :-)

I am just getting my first HF rig and am trying to decide what to get for an antenna. I am on a really tight budget so some things are out. I have been looking at the broadband folded dipole by B&W. I like the fact that it won't require a tuner. A couple of questions please. What do you think of this antenna? Does it tend to be directional? Which way is the best to use it, as an inverted V, flat, or sloper? Do you have any other suggestions for antennas? I live in west central South Carolina. Thanks for the read! Jon.

>The REAL question is: what RIGHT does this former TV repairman with no publishing record HAVE to 1) harass...

Not to be critical, but perhaps you'll explain for us why, in a public forum, Tom doesn't retain the right to question, challenge, and even make fun of you? Did you hesitate to mock Steve today? Do you have "special" rights others lack? Speaking of special, if publication count conveys privlege, you may relax and stand down. I have many more credits than you (starting in 1969), and so do several others on here. Hope that takes some pressure off.

>and libel<

You and your fractenna frat party have libeled many on here--viciously, repeatedly, and over a long period of time. So what? Am I suing you? Should I?

> 2) threaten my life?<

It would be extrodinarily easy to demonstate to any assembled panel of reasonable persons how your posts show an ongoing pattern of volatile and predacious retaliatory behavior laced with personal venom, libel, legal threats, false accusations, and even attempts to misuse police action. The truth is, nobody ever threatened on your life on here--and likely never will (it's a serious federal offense).

Personally, though, I'm a little worried about what you might attempt as a result of your pattern of making false claims--and so is my wife. Psychologists call it projection.

>Don't be diverted: I am not.<

Thank you. Every dipstick deserves a little oil.

>What is the conductivity of ordinary high strength
>structural concrete ? What is the permittivity ?

It varies depending on the aggregate used, porosity, and the proportions
of sand to mortar of the mix. In general, the aggregate contributes negligibly
to the conductivity of the concrete unless it is mill slag. In that case it contributes
strongly to conductivity. Porosity is important because the fluid in the pores is
about 10 times as conductive as the mortar paste. So the more porous (pores
on the order of 20 micrometers diameter) the cement, the higher the conductivity.
The ratio of sand to mortar is also important. The higher the ratio of sand to mortar,
the less conductive the concrete will be.

The conductivity of concrete will fall somewhere between 6 and 65 mS/m, with
the majority of high strength specimens clustering around 35 mS/m. So called
lightweight concrete (what the Ready Mix truck delivers), which contains more
sand, will cluster around about 15-20 mS/m.

Permitivity is more dependent on the exact aggregate used, and its size. Values
can range from as low as 3 to as high as 10 (ignoring mill slag). I don't have a
typical value for this, it varies regionally depending on the type of gravel typically
used in the area.

Then he didn't have a Code compliant Ufer. Remember, a minimum
of 20 lineal feet of minimum 1/2 inch diameter rebar, all electrically
joined and jacketed in a minimum of 2 inches of concrete is required
to form a Code compliant Ufer. If you just have a J bolt stuck down
in concrete, you don't have a Ufer, and local hotspotting can occur
during a strike.

What is the voltage between the tips of the meter probes?
The ASTM standard requires a minimum of 60 volts to avoid
errors due to polarization potentials. Measuring concrete or
soil resistance with a low voltage can give wildly incorrect
results.

>Is there some reference somewhere that shows concrete has less
>resistivity than soil?

Here are three.

1 G.E. Monfore, "The electrical resistivity of concrete," Journal of the PCA 10, 35-48, 1968.

2 H.W. Whittington, J. McCarter, and M.C. Forde, "The conduction of electricity through concrete",
Magazine of Concrete Research 33, 48-60, 1981.

3 I.L.H. Hansson and C.M. Hansson, "Electrical resistivity measurements of portland cement based materials," Cement and Concrete Research 13, 675-683, 1983.

(Yeah, I paid a visit to the Georgia Tech library.)

Source record: 179824

Chicken wire makes an excellent ground for feeding
and terminating Beverage antennas because of its high
capacitance to ground.

I'm personally familiar with a steerable narrow beamwidth
and low sidelobe military HF receiving system using an
array of 64 phased Beverages, each 220 feet long, 4 feet high a
nd 4 feet apart (side by side). The array occupies an area
about the size of a football field (the field was carefully excavated
to be almost perfectly level)..

The array beamwidth is a few degrees, steerable plus/minus
about 20 degrees from boresight, designed for use in the
mid to upper HF range. Longer Beverages would be needed
for lower frequencies (for example the 80 and 160 meter ham
bands).

The array is installed in an extremely rocky environment
where ground rods do not work. The array uses 40 feet of
chicken wire at both ends of each Beverage, laid directly on the
ground below the sloping ends of each Beverage at the feed
and the termination ends. The excellent performance of the array
was verified by elaborate measurements from an instrumented
helicopter.

Were the measurements published, or can they otherwise be obtained? Along with a detailed drawing or description of the antenna, this would provide a rare test of how well modeling programs deal with ground. Although good ground conductivity/dielectric constant measurements probably aren't available, they could be varied in the program for the best match, and we could at least see if some reasonable values do provide a match. One good set of measurements is much better than none!

Since I'm 75 miles from GA Tech, and since you've seen the books,
maybe you can tell us the figures they quote.

That was actually the question.

The Web page Wes mentions clearly states concrete has "fair"
conductivity, and Ufer grounds in the concrete should be augmented by
another ground.

From those numbers it looks like concrete is similar to regular dirt.

Yes. In this context it most certainly is.

The B&W uses a resistor to "broadband" the thing. It wastes power by tossing some of your RF power off as heat. Air colled dummy load. Write it off. Standard coax-fed dipoles for your favorite bands is one tried and proven route. A simple end-fed wire as high and long as you can manage to install tuned with one of the MFJ tuners against an equally simple couterpoise is an all-band solution which works quite well. Don't make the common mistake of limiting yourself to antennas with 50 ohm feedpoints. Assume the need for a tuner at the outset and the possibilities become endless.

THIS REALLY WORKS!!!!!!!!!!!! (9/6/00 04:40 PM EDT)
Email: bmullins@henry-net.com
Date: 9/222/00
Time: 6:35p.m.

Message:

READING THIS COULD CHANGE YOUR LIFE! I found this=20
on a=20
bulletin board and decided to try it. A little while back, I was =
browsing=20
through newsgroups, just like you are now, and came across an article=20
similar to this that said you could make thousands of dollars within=20
weeks with only an initial investment of $6.00! So I thought, "Yeah=20
right, this must be a scam", but like most of us, I was curious, so I =
kept=20
reading. Anyway, it said that you send $1.00 to each of the 6 names=20
and address stated in the article. You then place your own name and=20
address in the bottom of the list at #6, and post the article in at =
least=20
200 newsgroups. (There are thousands) No catch, that was it. So after=20
thinking it over, and talking to a few people first, I thought about =
trying=20
it. I figured: "what have I got to lose except 6 stamps and $6.00, =
right?"=20
Then I invested the measly $6.00. Well GUESS WHAT!!...within 7=20
days, I started getting money in the mail! I was shocked! I figured it=20
would end soon, but the money just kept coming in. In my first week, I=20
made about $25.00. By the end of the second week I had made a total=20
of over $1,000.00! In the third week I had over $10,000.00 and it's =
still
growing. This is now my fourth week and I have made a total of just=20
over $42,000.00 and it still coming in rapidly. It's certainly worth=20
$6.00, & 6 stamps, I have spent more than that on the lottery!! Let me=20
tell you how=20
this works and most importantly, why it works....Also, make sure you=20
print a copy of this article NOW, so you can get the information off of=20
it as you need it. I promise you that if you follow the directions =
exactly,=20
```

that you will start making more money than you thought possible by=20
doing something so easy! Suggestion: Read this entire message=20
carefully! (print it out or download it.) Follow the simple directions =
and=20
watch the money come in! It's easy. It's legal. And, your investment is=20
only $6.00 (Plus postage) IMPORTANT:=20
This is not a rip-off; it is not indecent; it is not illegal; and it is =
virtually=20
no risk - it really works!!!! If all of the following instructions are=20
adhered to, you will
receive extraordinary dividends. PLEASE NOTE: Please follow these
directions EXACTLY, and $50,000 or more can be yours in 20 to 60=20
days. This program remains successful because of the honesty and=20
integrity of the participants. Please continue its success by carefully=20
adhering to the instructions. You will now become part of the Mail=20
Order business. In this business your product is not solid and tangible, =

it's a service. You=20
are in the business of developing Mailing Lists. Many large=20
corporations are happy to pay big bucks for quality lists. However,=20
the money made from the
mailing lists is secondary to the income which is made from people=20
like you and me asking to be included in that list. Here are the 4 easy=20
steps to success: STEP 1: Get 6 separate pieces of paper and write the=20
following on each piece of paper "PLEASE PUT ME ON YOUR=20
MAILING LIST." Now get 6 US $1.00 bills and place ONE inside=20
EACH of the 6 pieces of paper so the bill will not be seen through the=20
envelope (to prevent thievery). Next, place one paper in each of the 6=20
envelopes and seal them. You should now have 6 sealed envelopes,=20
each with a piece of paper stating the above phrase, your name and=20
address, and a $1.00 bill. What you are doing is creating a service.=20
THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate=20
service and you are paying for it! Like most of us I was a little=20
skeptical and a little worried about the legal aspects of it all. So I=20
checked it out with the U.S. Post Office (1-800-725-2161) and they=20
confirmed that it is indeed legal! Mail the 6 envelopes to the following =

addresses:

#1) Samantha Blizniak, 7937 S. Newcastle, Burbank, IL 60459

#2)Katie Wiess, 14 White Tail Lane, Wallingford, CT 06492

#3)Traci Wood, 4224 Carnwath Rd., Tallahassee, FL 32303

#4)Milissa Crook, 3730 South 255th Place, Kent, WA 98032

#5)James Buckner, 11903 Coit RD. #1803 Dallas, TX 75251

#6)Bobbi Mullins, 31 Sunnydale Lane, Napoleon, OH 43545

STEP 2: Now take the #1 name off the list that you see above, move=20
the other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR=20

Name as number 6 on the list. STEP 3: Change anything you need to,=20
but try to keep this article as close to original as possible. Now, post =

your amended article to at least 200 newsgroups. (I think there are=20
close to 24,000 groups) All you need is 200, but remember, the more=20
you post, the more money you make! This is perfectly legal! If you=20
have any doubts, refer to Title 18 Sec. 1302 & 1341 of the Postal=20
lottery laws. Keep a copy of these steps for yourself and, whenever=20
you need money, you can use it again, and again. PLEASE
REMEMBER that this program remains successful because of the=20
honesty & integrity of the participants & by their carefully adhering to =

the directions. Look at it this way. If you are of integrity, the =
program=20
will continue and the money that so many others have received will=20
come your way. NOTE: You may want to retain every name and=20
address sent to you, either on a computer or hard copy and keep the=20
notes people send you. This VERIFIES that you are truly providing a=20
service. (Also, it might be a good idea to wrap the $1 bill in dark =
paper=20
to reduce the risk of mail theft.) So, as each post is downloaded and =
the=20
directions carefully followed, six members will be reimbursed for their=20
participation as a List Developer with one dollar each. Your name will=20
move up the list geometrically so that when your name reaches the #1=20
position you will be receiving thousands of dollars in CASH!!! What an=20
opportunity for only $6.00 ($1.00 for each of the first six=20
people listed above) Send it now, add your own name to the list and=20
you're in business!=20
---DIRECTIONS -----=20
FOR HOW TO POST TO NEWSGROUPS----------=20
Step 1) You do not need to re-type this entire letter to do your own=20
posting. Simply put your cursor at the beginning of this letter and drag =

your cursor to the bottom of this document, and select 'copy' from the=20
edit menu. This will copy the entire letter into the computer's memory.
Step 2) Open a blank 'notepad' file and place your cursor at the top of=20
the blank page. From the 'edit' menu select 'paste'. This will paste a=20
copy of the letter into notepad so that you can add your name to the
list.=20
Step 3) Save your new notepad file as a .txt file. If you want to do =
your=20
postings in different settings, you'll always have this file to go back =
to.=20
Step 4) Use Netscape or Internet explorer and try searching for various=20
newsgroups (on-line forums, message boards, chat sites, discussions.)
Step 5) Visit these message boards and post this article as a new=20
message by highlighting the text of this letter and selecting paste from =

the edit menu. Fill in the Subject, this will be the header that =
everyone=20

sees as they scroll through the list of postings in a particular group,
click the post message button. You're done with your first one!
Congratulations...THAT'S IT! All you have to do is jump to different=20
newsgroups and post away, after you get the hang of it, it will take=20
about 30 seconds for each newsgroup! **REMEMBER, THE MORE=20
NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL=20
MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** That's=20
it! You will begin receiving money from around the world within days!=20
You may eventually want to rent a P.O.Box due to the large amount of=20
mail you will receive. If you wish to stay anonymous, you can invent a=20
name to use, as long as the postman will deliver it. **JUST MAKE
SURE ALL THE ADDRESSES ARE=20
CORRECT.** Now the WHY part: Out of 200 postings, say I receive=20
only 5 replies (a very low example). So then I made $5.00 with my
name at #6 on the letter. Now, each of the 5 persons who just sent me=20
$1.00 make the MINIMUM 200 postings, each with my name at #5=20
and only 5 persons respond to each of the original 5, that is another=20
$25.00 for me, now those 25 each make 200 MINIMUM posts with=20
my name at #4 and only 5 replies each, I will bring in an additional=20
$125.00! Now, those 125 persons turn around and post the MINIMUM=20
200 with my name at #3 and only receive 5 replies each, I will make an=20
additional $626.00! OK, now here is the fun part, each of those 625=20
persons post a MINIMUM 200 letters with my name at #2 and they=20
each only receive 5 replies, that just made me $3,125.00!!!=20
Those 3,125 persons will all deliver this message to 200 newsgroups
with my name at #1 and if still 5 persons per 200 newsgroups react I=20
will receive $15,625,00! With an original investment of only $6.00!=20
AMAZING! When your name is no longer on the list, you just take the=20
latest posting in the newsgroups, and send out another $6.00 to names=20
on the list, putting your name at number 6 again. And start posting=20
again. The thing to remember is: do you realize that thousands of=20
people all over the world are joining the internet and reading these
articles everyday?, JUST LIKE YOU are now!! So, can you afford
$6.00 and see if it really works?? I think so... People have said, "what
if the plan is played out and no one sends you the money? So what!
What are the chances of that happening when there are tons of new
honest users and new honest people who are joining the internet and
newsgroups everyday and are willing to give it a try? Estimates are at=20
20,000 to 50,000 new users, every day, with thousands of those
joining the actual internet.Remember, play FAIRLY and HONESTLY
and this will really work

it's a service. You=20

are in the business of developing =
Mailing=20
Lists. Many large
corporations =
are happy to=20
pay big bucks for quality lists. However,
the=20
money made from the
mailing lists =
is secondary=20
to the income which is made from people
like=20
you and me asking to be included in that list. Here are the 4 easy=20

steps to success: STEP 1: Get 6 =
separate=20
pieces of paper and write the
following on=20
each piece of paper "PLEASE PUT ME ON YOUR
MAILING LIST." Now get 6 US $1.00 bills and place ONE inside=20

EACH of the 6 pieces of paper so =
the bill=20
will not be seen through the
envelope (to=20
prevent thievery). Next, place one paper in each of the 6 =

envelopes and seal them. You should now have 6 =
sealed=20
envelopes,
each with a piece of =
paper stating=20
the above phrase, your name and
address, and=20
a $1.00 bill. What you are doing is creating a service.
THIS IS ABSOLUTELY LEGAL! You are requesting a =
legitimate=20

service and you are paying for =
it! Like most=20
of us I was a little
skeptical =
and a little=20
worried about the legal aspects of it all. So I
checked it out with the U.S. Post Office (1-800-725-2161) and =
they=20

confirmed that it is indeed =
legal! Mail the 6=20
envelopes to the following
addresses:

#1) =
Samantha Blizniak,=20
7937 S. Newcastle, Burbank, IL 60459

#2)Katie Wiess, 14 White Tail Lane, Wallingford, CT=20
06492

#3)Traci Wood, 4224 =
Carnwath Rd.,=20
Tallahassee, FL 32303

#4)Milissa Crook, 3730 South 255th =
Place, Kent,=20
WA 98032

#5)James Buckner, =
11903 Coit RD.=20
#1803 Dallas, TX 75251

#6)Bobbi Mullins, 31 Sunnydale Lane, Napoleon, OH =
43545

STEP 2: Now take the #1 name off the list that you =
see above,=20
move
the other names up (6 =
becomes 5, 5=20
becomes 4, etc...) and add YOUR
Name as=20
number 6 on the list. STEP 3: Change anything you need to, =

but try to keep this article as close to original =
as possible.=20
Now, post
your amended article to =
at least=20
200 newsgroups. (I think there are
close to=20
24,000 groups) All you need is 200, but remember, the more =

you post, the more money you make! This is =
perfectly legal! If=20
you
have any doubts, refer to =
Title 18 Sec.=20
1302 & 1341 of the Postal
lottery laws.=20
Keep a copy of these steps for yourself and, whenever
you need money, you can use it again, and again.=20
PLEASE
REMEMBER that this program =
remains=20
successful because of the
honesty =
&=20
integrity of the participants & by their carefully adhering to=20

the directions. Look at it this =
way. If you=20
are of integrity, the program
will continue=20
and the money that so many others have received will
come your way. NOTE: You may want to retain every name and=20

address sent to you, either on a =
computer or=20
hard copy and keep the
notes =
people send you.=20
This VERIFIES that you are truly providing a
service. (Also, it might be a good idea to wrap the $1 bill in =
dark paper=20

to reduce the risk of mail =
theft.) So, as=20
each post is downloaded and the
directions=20
carefully followed, six members will be reimbursed for their =

participation as a List Developer with one dollar =
each. Your=20
name will
move up the list =
geometrically so=20
that when your name reaches the #1
position=20
you will be receiving thousands of dollars in CASH!!! What an =

opportunity for only $6.00 ($1.00 for each of the =
first six=20

people listed above) Send it now, =
add your=20

own name to the list and
you're =
in business!=20

---DIRECTIONS ----- =

FOR HOW TO POST TO NEWSGROUPS---------- =

Step 1) You do not need to re-type this entire =
letter to do=20
your own
posting. Simply put your =
cursor at=20
the beginning of this letter and drag
your=20
cursor to the bottom of this document, and select 'copy' from the=20

edit menu. This will copy the =
entire letter=20
into the computer's memory.
Step =
2) Open a=20
blank 'notepad' file and place your cursor at the top of =

the blank page. From the 'edit' menu select =
'paste'. This will=20
paste a
copy of the letter into =
notepad so=20
that you can add your name to the
list.=20

Step 3) Save your new notepad =
file as a .txt=20
file. If you want to do your
postings in=20
different settings, you'll always have this file to go back to. =

Step 4) Use Netscape or Internet explorer and try =
searching=20
for various
newsgroups (on-line =
forums,=20
message boards, chat sites, discussions.)
Step=20
5) Visit these message boards and post this article as a new =

message by highlighting the text of this letter =
and selecting=20
paste from
the edit menu. Fill in =
the=20
Subject, this will be the header that everyone

sees as they scroll through the list of postings in a =
particular=20
group,
click the post message =
button. You're=20
done with your first one!
Congratulations...THAT'S IT! All you have to do is jump to =
different=20

newsgroups and post away, after =
you get the=20
hang of it, it will take
about 30 =
seconds for=20
each newsgroup! **REMEMBER, THE MORE
NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL =

MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** =
That's=20

it! You will begin receiving =
money from=20
around the world within days!
You =
may=20
eventually want to rent a P.O.Box due to the large amount of =

mail you will receive. If you wish to stay =
anonymous, you can=20
invent a
name to use, as long as =
the postman=20
will deliver it. **JUST MAKE
SURE =
ALL THE=20
ADDRESSES ARE
CORRECT.** Now the =
WHY part:=20
Out of 200 postings, say I receive
only 5=20
replies (a very low example). So then I made $5.00 with =
my
name at #6 on the letter. Now, each of the 5 =
persons who just=20
sent me
$1.00 make the MINIMUM =
200 postings,=20
each with my name at #5
and only =
5 persons=20
respond to each of the original 5, that is another

$25.00 for me, now those 25 each make 200 MINIMUM posts with=20

my name at #4 and only 5 replies =
each, I will=20
bring in an additional
$125.00! =
Now, those=20
125 persons turn around and post the MINIMUM
200 with my name at #3 and only receive 5 replies each, I will =
make an=20

additional $626.00! OK, now here =
is the fun=20
part, each of those 625
persons =
post a=20
MINIMUM 200 letters with my name at #2 and they
each only receive 5 replies, that just made me $3,125.00!!!=20

Those 3,125 persons will all =
deliver this=20
message to 200 newsgroups
with my =
name at #1=20
and if still 5 persons per 200 newsgroups react I
will receive $15,625,00! With an original investment of only =
$6.00!=20

AMAZING! When your name is no =
longer on the=20
list, you just take the

Tom,
In this part of the country you could be lynched for using the term
"dirt" in describing the countryside. I can only assume nothing
grows where.you live.
With regard to the use of concrete laced with reinforcement as
a suitable ground connection, swimming pools are the exception here
so are not used to tie a tower legs to ground, concrete seems
to be the next best thing. Certainly better than just a hole in the,
how is it that you say it ....."dirt".
As concrete retains moisture its use has even more going for it
With respect to voltage levels used for testing purposes, there
is many an engineer out there that state, in error, that an electrical
contact is mechanically open when using a Simpson
that uses" low " (battery) voltage levels to test continuity

Well, that casts a completely different light on your question.
For free, the B&W is probably not all that bad. It is useful
on some bands. It's just not worth the retail price, IMO.

I am thinking about buying a High Sierra 1500 antenna for use at my house.
I will be mounting this as a temporary antenna using a tripod and 1.25" mast
at either 15 or 25 feet.

I would like any comments from anyone who has used this antenna is a
non-vehicle configuration. What kind of radials / counterpoise, if any, is
needed.

Tnx

High Sierra actually has a system for fixed use that is more efficient
than a mobile antenna.

> I would like any comments from anyone who has used this antenna is a

Art Unwin wrote:
"Am I skating on thin ice---?"

Depth of wave penetration depends on wavelength, dielectric constant, and conductivity. The soil behaves as a leaky capacitor. Depth ranges from a few feet at the highest frequencies used for sky-wave communications, to hundreds of feet at AM broadcast and lower frequencies. The quality of reflection produced by the earth is affected by conductivity, dielectric constant, frequency, wave polarization, angle of incidence of the wave and reflecting surface, etc.

A perfect ground reflector will completely cancel the incident wave at its surface if that wave is horizontally polarized and if the incidence angle is small.

At small angles with the surface, the incident and reflected waves at a perfectly reflecting ground surface will add if vertically polarized.

What happens when water on the surface, or saturating the crust, of ground under and in the vicinity of a vertical antenna freezes, depends on the percentage of the wave penetration depth the frost occupies.

It may come as a surprise that sometimes AM broadcast endineers are advised to establish field strength monitoring points for stations in the northern U.S. during winter. The frost often brings higher field strength readings. Thus seasonal changes won`t likely put one of the stations in violation from excessive monitoring point field strength readings. Their actual high readings will have already been cleared in the proof of performance.

Are you talking about the system they have in a big field in (I think) Gaithersburg? Wouldn't there be some implications involving the feds having difficulty hearing w1s from that locale on 28Mhz? w1s are very scarce here in Philly on 28Mhz, they skip right over us.

If the loss isn't in the transmission line, where is it? My commercial rig has an ALC, and it produces 100 watts out into any load, provided that the mismatch isn't so large as to make it shut down. The rig's efficiency might be a little less (or more) when presented with a 1.8:1 mismatch, but why should I care?

Come on, now. The equation I posted can be solved on a $4.99 scientific calculator. With a piece of graph paper, you could have a pattern in five minutes.

I do heartily agree, though, that it's extremely important and useful to also have a qualitative and intuitive idea of what's going on.

Big deal. When we are at solar max, like now, 10M is open to anything.

Last solar max I was doing a LOT of traveling. I bought a HTX-100 (25W for
those that aren't familiar with it), made a dipole out of Radio Shack
speaker wire, soldered a small lug to each end, and thumb tacked it to
the wall of whatever hotel/motel I happened to be in at the time. I also
cut down one of the short Radio Shack CB mag mount antennas so I could
do mobile in rental cars.

I managed to basically "work the world" with this high-tech setup in what
little spare time I had.

I am NOT impressed with working a lot of stations on 10M during a solar max.
The antenna has almost NOTHING to do with it nor is it any indication of how
well, or badly, the antenna works.

Greetings to all who read this!

I am considering building a dipole with a pair of
20 meter HF mobile whips and feed it with
450 ohm feed line so I could use the configuration
to 10 meters.

Questions to ponder:
Has any one on this reflector ever constructed a
contraptions as this?
How effective was this antenna?
Would 300 ohm feed line have been a better choice?
Was a balun needed?

Thanks in advance

Christopher Moseley wrote:
"I was thinking of making a two element yagi, using the telescoping elements from television dipoles."

Arnold B. Bailey produced an excellent book: "TV and Other Receiving Antennas" which has a catalog of designs all centered on 200 MHz. For 100 MHz, you need to multiply most of the dimensions by two.

Bailey classifies his horizontal dipole with a parasitic reflector as a horizontally polarized directional antenna. Its pattern has substantial forward gain but modest rear suppression.
Description: Horizontal center-fed half-wave tube in front of parallel half-wave tube.
Size at 200 MHz: Connected element: 25.4 inches long, 0.5-inch diameter.
Parasitic: 29.9 inches long, 0.5-inch diameter.
Spacing: 12 inches between axes.
Transmission line: Matching section required.
Resistance at center frequency: 28 ohms.
Antenna average surge impedance: 300 ohms.
Gain at center frequency: 5 dbd.
Frequency bandwidth: 1 db down, 15%, 3 db down, 33%.

Near identical characteristics are obtained by using a folded dipole as the driven element to quadruple the drivepoint impedance as this may in some cases ease the impedance matching to the feedline.

This dipole with parasitic reflector was described by G.H. Brown in Volume 25, Page 78 of Proc. IRE, Jan. 1937.

The NG should be aware that this offer is a lie. He offered the EZNEC file for one of his antennas to the group (yep- public offer) under the same set-up- ie, join his private list.

I did just that, and found a post that said to ask Chip, directly. I did. Chip answered, said he would send the file, in "a couple of days".

After four days, I sent him a query-(on his list)- no answer. Knowing he monitored this NG, I asked him the same question, here- ie, did he forget to send it to me?)

HIs response was to ban me from the list- tell me I would NEVER get the file- the reason being that I had posted an offer for him (chip) to provide the file, to THE WHOLE WORLD !!. Another Chipper lie.

He was the one that made the offe, not me- He was apparently looking for an excuse to ban me, but he picked a silly one, with no truth.

However- I am not asking back on his list- nor do I need his file- I have no respect for his censored (heavily, by him)list, or him, and I got a very usable copy elsewhere. All the shotcomings of the antenna, found by others, proved to be true.

I hope this helps.

Possible mismatch loss in the amp because a Z0-match doesn't
exist and the amp is not seeing its designed-for load.

Damn, looks like someone forgot Rule #1 again.

Rule #1 Chip is always right.
Rule #2 In case of any question, see Rule #1.

It would be better to use 10m mobile whips. Using 20m Hamsticks (for instance) on 10m may result in self-resonance, a lossy condition where the inductance and distributed capacitance pass energy between them resulting in unacceptable losses. I don't know exactly what the self-resonant frequency of a 20m Hamstick is. Does anyone know?

If you want a 20m-10m antenna, simply put up a 33 ft center-fed dipole fed with ladder-line with a choke at the coax/ladder-line junction. That's what I have and it's rotatable.

Some more of Chips purposful misreading shows up in the latest. I have cut out much of this post, but have NOT changed the following "BIg Lie" paragraph. I have read the original posts that Chip is supposedly refering tohere, and he has either misread them, or is lieing.

Fractenna wrote: In part:

> If he has something then show us. As I scientist I will respond, in praise, or
>
> Nathan Cohen, Ph.D.

NO1- THe design with the helical windings was not in contention- just an interesting side issue- Chip has also refered to this one as a nine foot loop, which is hilarious.
No2. The design is not purely random, but was made by a random process. THe file has been made available more readily than the ones Chip has.
No3 THis is a BIG LIE- the design in question IS 2d- the word"almost" does NOT modify the symbol "2d" in the original. Any continued reference like this from Chip is a lie, and he knows it.
no4- Only you, Chip, believe otherwise. The analysis says different.

Clean up your act, Chip, and you may gain back some respect- (when hell next freezes over)

It is time for Dr. Cohen to act like a scientist and stop diverting the issue.
He should also give the Doctorate of Steve its respect- he does that for you when he uses any honorific. Calling him "Mr. Best" is just a subtle, calculated insult.

I hope this helps.

I used (and still have) an AEA Isoloop that worked real well on a 3 story apartment while on a consulting job in northern CA. It is a very good antenna but requiring care while tuning. AEA added a Isotuner with DOS based software that makes it a lot easier. Disadvantage is maximum of 150 watts and also I think they are now out of business. I recently saw one of these computer versions sold for around $200 here on newsgroup. There are a couple still made by other manufactures.

I should have added that this is a volume resistivity measurement, so the volumes should be the same. Your concrete sample should have the same volume as the Earth. The only way to achieve this is to reduce the volume of the Earth by one-half and replace it with concrete.

The industrialized nations are working on this.

Cheers,

Wes

> Your implying that you *helped* is disgraceful.

Danny,

I think you are assuming Chip had a motive to deceive.
While it is possible that such a motive existed or exists,
there is an awful lot of evidence that something else
is going on.

First, I must state that I, too, thought Chip implied that
he assisted Sara. However, consider this: Fractenna,
including Chip, NC, et al has never shown a good ability to
communicate clearly on the NG. Posts from Fractenna are

so often off the mark that I believe this is just one more case. He/they/it - whomever at Fractenna does not understand what is posted by others, either. Witness the response from NC to you on this. You never made the assertion in your post that NC sees in it.

I think this is just one more example of poor communication from Fractenna, after reading it over several times carefully. I think Chips motive was pure. I believe he was genuinely pleased to find out about the project, and I don't think he was purposely attempting to imply that he helped. There is no doubt that he is enthusiastic about fractal antenna designs - but he is the world's worst "salesman" at getting the folks on this NG excited about it. I needn't rehash what he does that turns people off so much. Suffice it to say that he can't "listen" because his mind is closed.

But I do not believe his post was made with a dishonest motive.

Sideband- please dont assume that a non-ideal EWR indicates lots of
loss. It just is not true. Several facts are:
1. If the rig is working into the 1.8, and not cutting power back, its
not doing much harm.
1. The 1.8 figure is with respect to an instrument matched to 50 Ohms.
With a normal dipole , a 1:1 is not possibel, without some kind of
transformation.
3. a 1:1 choke balun is probably indicated, to keep the common mode
current down. It will probably help the RFI, also.

Good LUck- Bill-W4BSG

============================

Well, it would be like that, were it not for the high
attenuation of radio waves as they pass through the soil or
dirt.

Think in terms of 60 dB per free-space wavelength and you
don't get much further than the RF skin depth in the topmost
layer of soil. At 30 MHz that's only a few feet.

Tom, W8JI is reputed to have said (It hasn`t appeared on my screen yet):
"Losses in the soil act like a large lossy media with phase shift.
Visulizing the soil as a "leaky capacitor" paints a poor mental image of
what really goes on."

A measurement of electric current which results from electron movements
presents a poor mental image of what really goes on, too. But, current
measurements are useful.

So, we have phase shifts and complex quantities which describe them.
These can be represented by vectors. Vectors con be resolved into their
axial components which can then be composed into a resultant.

The soil involved in radio propagation has been characterized by Terman
as a "leaky capacitor", so that`s good enough for me.

Best regards, Richard Harrison, KB5WZI

Nah, they are getting more and more broad minded and less discriminatory.

They go after Netscape and even some are turning up for LINUX. and Apples.
You can tell when an OS is becoming well used when the viruses start showing
up for them. <:-))

Although, I think (I was wrong one time) Outlook and Outlook Express are
more prone to the embedded text file worms, but Norton is real good at
catching those.

The impedance will depend on the environemnt--including the height above ground.

It's rare to actually see a HF dipole with a 70 plus ohm resonance. But again--depends on height.

O.k. I have done some playing and this is what I found. In an attempt to hide the coax there was a small (2 foot section) that ran parallel to the dipole. It was about 2 feet away but when I pulled it down so the coax droped straight down from the feed point the resistance went up to 40 Ohms (it was 30 Ohms) and the SWR dropped to approx. 1.45 :1 at 50.15 MHz which is my center frequency. I got hold of a copy of the ARRL handbook , as was suggested in an email, and was looking at baluns like Bill Aycock had suggested and there was a line in there about them often being used when the feed line was not perfectly perpendicular to the dipole. Well, as soon as I saw that I knew what I had to try first and it helped a bunch. I can live with this. Now I need to get a local ham to try a qso with because I am still not hearing anything and nobody answers my CQ. Maybe this area (Chicago suburbs) is not very active on 6 meters? Maybe the antenna isn't turned the right direction to get anything. I have a brick wall about 4 feet behind it and another brick building across the street. I was kind of hoping for some reflections since my 2 meter dual band antenna in about the same place talks all over except directly behind me. Oh well. I know the location isn't ideal but I won't live here forever. I am still going to experiment with those other antenna ideas and see what happens. Thanks again to all that replied both here and by email. I was pleasantly suprised by the quick turn around time as I was expecting this to go on for about a week.

I just happened to look into this the other day with the modeling. As
far as I can tell, every time you double the amount of radials, you gain
about .4 db. "over good ground" But this varies a bit. Going from 4
radials to 60 will be appx 2.7 db. Almost equal to doubling your power.
Of course, doubling your power can mean little in some cases, but it can
mean everything in other borderline copy scenarios. Few radials can work
fine in many cases, but a lot of them works better. Are they necessary?
Depends how good a station you want. The broadcasters don't use a lot of
them for nothing. If it didn't make a difference, they wouldn't waste
the money. MK

If I remember correctly , in my communications class at DeVry they said it was a redundancy thing. To be effective they had to have X number and the rules state that number had to be doubled. Now mind you this was a class I took 7 years ago when I had little interest in radio. I would be interested in the actual answer (now that I have an interest) if there is anyone that knows about broadcast installations and FCC regs.

>BTW Rick, any idea who the idiots were who QRM'ed me this morning? I am not assuming it was you.<

You are correct (I'm not THAT stupid). In fact, whatever happened, I must have missed it. I tuned across you and stopped to listen for a few minutes before moving up the band, and your frequency was pretty clear of QRM.

I did swing the beam south and listen to your audio again to see if I could discern any EQ difference between the voice keyer and the mic. This time, I opened up my passband and could hear a slight change. When I reset the filtering to where I normally keep it, I didn't hear it anymore. It's there, but pretty minor--I doubt anyone would notice unless they were listening for it.

Hello Dick--

No; Ii didn't even suggest he was QRMing me this morning; i was wondering if he might know who was. That's what I ask. Please read my post again.

It was a pretty sincere question, as Rick seems to monitor quite a few of my 10M activities.

Thanks on audio;

Just so you know, the idiocy was so far from your operating behavior that it never occurred to me that it was you.

The FCC has a real time location system using interferometry. I think if more hams knew this there would be less malicious interference.

Joe, What percentage of the signal is lost due to an SWR of 1.8:1?
Answer: Neglecting feedline losses, a maximum of 8%, i.e. less than
one watt or about 1/3 of one dB.

Moral: An SWR of 1.8:1 is acceptable for almost all applications.
You will still be radiating approximately 9 watts. I would go
ahead and use it as is.

>Wouldn't a Moxon rectangle be a lot easier to build? I'm sure it would give the same performance and be small also, but very much easier to build.<

Having built one for 10-M, I think Moxon Rectangels are pretty easy. I used smaller diameter tubing than LB Cebik prescribed his and telescoped each end section just before the 90-degree bend so I could tune it and also align the tips more easily. Used a chapo tubing bender to form the 90's instead of the pre-bent widgets LB used. Took me an afternoon to build and tune, weighed about 2 pounds, worked great.

At VHF, Moxons make great handheld DF antennas because they are compact and have a deep backnull. Good for vertical sidemount, too.

In fairness, I don't know what kind of effort a 10-M FQY would take--my fractal construction experience has all been at VHF.

Jerry,

In general, the orientation of the inside part of the glass-mount is
irrelevant, but should be at least and inch from the edge of the
window. The 70cm "radial" should be oriented parallel to the horizon
for best gain. Note: the antenna will work fine without this, but the
gain on 70cm will be reduced considerably. Most of these thru-glass
antennas have about 0.5 db loss in the coupling, and have around 2.2 dB
gain (dbi) on 2m and around 4.5 dB gain on 70cm when the "radial" is
installed.

Well, those "broadcast days" engineering plus later work by Jerry Sevick prompted me to go to 60 radials in order to gain about 2-3 db less ground loss. Here in North Central Texas, especially in the summers, we have very dry and hard topsoil and attendent high ground loss. A ground rod just doesn't do it around here.

When you are running a max of 100 watts, as I am, that can be important. Since much of my operating is QRP, it really becomes important. It ultimately becomes a question of what performance you are seeking and your willingness to do what it takes to achieve that level.

Keep in mind that the Butternut radial kit of 4 radials is designed and recommended on the basis that the radials will be part of an overall *elevated* installation of the antenna and the radials. This does not translate into 4 radials being "enough" in a ground environment.

Others on the NG have commented on this matter.

Glad your antenna worked so well. By the way, my radial farm occupies zero space above ground . . .

That system was pretty well outlined in QST a while back--and the FCC is currently actively using it on 10 to nail freebanders. I used to run nets and put up with that crap, so I don't have much respect for it.

Anybody remember the story floating around awhile back about a drunken swapnet QRMer forced at gunpoint by the hams who caught him to smash his equipment with a sledge hammer? Probably an urban myth, but it always gave me a warm feeling. Now Mr. Hollingsworth gives me a warm feeling.

Hi Marc,

A Bobtail is pretty lossy unless you get it well up above earth (in terms of the wavelength). Maybe 1/4 wl above ground at the element tips.

Other than that a ground screen helps.

Feeding it with coax at the tope of the vertical center section is a pain, because the feedline will almost always couple to the antenna. The only way around that is a high impedance choke balun at a couple points on the feedline, or pulling the feedline out away from the antenna at or above the height of the top for a good distance before dropping it down.

I prefer bottom feeding the center element through a matching network, working it against a fairly decent radial system. I think you would do better on 15 meters with a high dipole or perhaps an EDZ antenna. I've never found Bobtails to work as well as some claim.

Eyewitnesses said it was a blurry rotation of wind--no dust or cloud-- about 40 feet wide. The trees were about 20 and 40 feet from the house.

The house sustained some damage but it skimmed it mostly

I was looking out the widnow and saw all the tres and bushes go sideways for a few seconds. It was weird.

Someone e-mailed me this, but he wants to remain unnamed to the
general public:

I didn't want to get into a clusterfight on the NG with this one, and
thot
you might get a chuckle. You can quote me without attribution <BG>.

After the Ufer experience on the NG, of last year, several of us
interested
in high-energy discharges wanted to find out whether vaporizing metal
inside
concrete could rupture the surrounding jacket.

Back in June, we experimented to find out how many joules it took to
vaporize a 2ft length of #10 copper on discharge. My ears are still
ringing <G>. Nice plasma!

We made a number of I-shaped concrete (5-bag, crusher-run) pieces,
about
a
foot long and an inch and a half square, with pieces of #10 copper
wire
in
their centers. Cured 'em properly.

The results give a whole new meaning to 'fragging'. The largest
chunk
of
concrete we could find was maybe a half inch across. The devastation
was
complete. Ain't no pictures cuz the chunk above took out the camera
:-(

Sure beats the tantalum-capacitor substitutes I've been using for M80s
and
blasting caps on halloween and other occasions. The noise
approximates
a
20-pound cannon shot -- I couldn't tell the difference.

I can see why someone might be nervous about depending totally on a
Ufer
ground for lightning protection. It didn't take all that many joules
to
frag the concrete.

End....

Still looking for tests or data.

Sounds like a real nasty tornado! I'm amazed anything survived!!!!

Anyway, despite the wide swath of destruction, at least it makes great
advertising hype.

My antennas have withstood a few F1 tornados like that also! They
occur a few times a year here. Some have blown down one foot diameter
trees!

If the intruders are all still walking around free men, I suspect it
is an urban myth.

The FCC rarely used the I-net system on amateur bands. It is busy most
of the time doing important things. It takes me about a week or so to
get them to look at problems like continuous jammers on things like
WWV, I imagine they care less about one ham being bothered by QRM for
a few minutes. It took four weeks to schedule it for a BC IMD problem
in Chattanooga, and I have the direct number to I-net.

Especially when that ham has a history of exaggerating the truth and
says he has filed what amount to false police reports.

> formula? I can see what the answers are, but I want to know how I can
> derive them.

You have gotten good answers to this question from Jim, Roy and Richard. I think they keyed off of your word "derive", which usually implies a rather rigorous mathematical treatment. May I suggest a few rules of thumb (heuristics) that I have found useful in approaching these problems:

Looking at the antennas from the top (they would be two dots on a piece of paper), draw a line between them and then another line perpendicular to and bisecting that first line.

Consider measuring points anywhere along that perpendicular line.

If the antennas are fed IN-PHASE (at 0 degrees phase shift), the signals from the two antennas will be precisely in-phase with each other and add constructively along that line. At any other points, the phasing will be off, the addition will be less than perfect and the resulting signal will be less than maximum.

Therefore, for in-phase antennas, the maximum radiation will always occur in the direction perpendicular to the line connecting them. This is true whether the antennas are 1/4 or 1/2 wavelength apart.

Next consider the case where the antennas are fed OUT-OF-PHASE (at 180 degrees phase shift) and separated from each other by 1/2 wavelength. Along that same perpendicular line the signals from the two antennas will be precisely 180 degrees out of phase and will completely cancel each other, producing a null in the combined response in that direction.

On the other hand, at each antenna, the signal from the other antenna will have been shifted an additional 180 degrees by traveling the 1/2 wavelength between them and will now be in-phase with the signal from that antenna. The signals reinforce each other and produce maximum responses in both directions of the line joining them.

Although the above considered 1/2-wavelength-spaced antennas, the same holds true for closer spacings and 180-degree phase

shifts in feeds.

The case of antennas separated by 1/4 wavelength and fed 90 degrees out of phase is somewhat special. It produces a unidirectional response in the direction of the line between the two antennas. In one direction of that line is a null produced by the two signals cancelling one another. In the other direction is the maximum response due to both signals adding in-phase.

The exam question doesn't go into which direction is which, but the way to tell is to compare the phase of the signal of the first antenna to that of the signal in the second one after the first one has been delayed by an additional 90 degrees due to traveling the 1/4-wavelength distance. If they cancel each other, that direction (first-to-second) is the null. If they add, the first-to-second direction is that of maximum response.

I am a firm believer in being able to arrive at specific answers from first principles. However, that doesn't necessarily mean manipulating complex equations, particularly when the question isn't asking for precise answers. A little bit of pencil-and-paper geometry goes a long way here.

3041. Antenna Stacking advice needed

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-24 00:00:00 UTC
From: Bruce Brackin <bbrackin@bellsouth.net>
Message-ID: <39CE8E89.2E01F1B2@bellsouth.net>
Source record: 179713

Greetings - Have a 6 meter beam, 2 meter beam and triband vertical (6/2/70cm) I would like to get on common rotor mast. Looking for advice on seperation/spacing of these antennas. The 6M beam is 15' boom - 6 element LP, hort. polarized. 2 meter is 12' boom -10 element yagi vertically polarized. Triband vertical has 3 radials - one long (counterpoise) for tuning 6 meter. Total wind load of all is about 4 sq feet.

Have always heard and read the 1/2 boom length rule. Any difference on positioning vert polarized (2 m) over a horizontal one (6 m). Figure the vertical triband can be relatively close to 2m beam because of short radials/counterpoise. Don't want to use a mast any longer than I need to.

Thanks - Bruce, KD5IUG

Source record: 179769

Hey John,

You might not remember me, but I am Alistair White's older brother Will. I am living in Arizona, but am quite familiar with the problem you have there. I used to have several wire antennas on top of our house on Pierrepont St., and never tried a vertical for the reasons you state. Any commercial vertical ought to work fine, in terms of communications performance.

You ought to look at the advertised wind load/wind survival figures, but many many hams run verticals on top of tall buildings or other structures like towers, and they survive the wind quite well. You probably want to mount the antenna on a >10' 2" thick galvanized mast, with the mast mounted either to a tripod or via straps and clamps to a chimney or other rooftop projection.

Guying will obviously be neccesary to effect a strong, durable installation. Be sure to check charts such as published in the ARRL Antenna Book for certain resonant lengths of guy line to avoid. Radials, or one of the counterpoise "kits" the various antenna manufacturers sell, are absolutely necessary if you want even moderate performance from a vertical monopole. They aren't such a pain in the ass as many people seem to think they are. As for particular models, I used to have a Butternut, and that worked great for me, if a bit narrow-banded on 75M.

I have known several hams who have had good results with either a Butternut, or a Cushcraft R-7000. The height of your building is a definite plus, and if I had that advantage, I would consider a wire inverted-V fed with ladderline or twinlead via a decent tuner, perhaps mounted on top of a push up mast. It is significantly cheaper an antenna, has better wind survival, is no harder to install than a vertical with radials, is nearly as omnidirectional as the vertical, and has the advantages of being more efficient, offers wider bandwidth, and is slightly less prone to noise pickup, especially in an RF-noisy urban environment like yours. Hope this helps.

> defer to those more
> knowledgeable. :-)

At resonance (for all practical purposes, the point at which the SWR is lowest), a half wave dipole will typically have an input resistance of around 50 - 100 ohms, depending on height and ground characteristics. So an SWR of 1.8:1 isn't surprising. Since it goes up in either direction as you change frequency, you won't be able to do any better than this by adjusting the element lengths. Changing the antenna height might make it go either up or down, but trading SWR for a lower antenna is a bad trade.

Also, can you think of anything that will help to
> lower this SWR?
> Grounding something? Standing on my head in a bucket of water? :-)

Build or buy an antenna tuner (transmatch), or build a simple L network for matching. You can find information about this in the ARRL Antenna Book. But why bother? Unless your feedline is really long or really small, or unless your transmitter won't deliver full power into 1.8:1 (unlikely), lowering the SWR won't accomplish anything at all.

> I
> have not
> been able to even hear anything on the radio yet let alone make any
> contacts and

> wonder if this is part of my problem.

Nope. The SWR isn't your problem. If I were you I'd stop fiddling with the SWR and look elsewhere. Is your radio broken? Where do you live? Is there a lot of 6 meter activity there? Can you make arrangements for a schedule with a local ham to test your rig?

> I know the location and height

The signal will be strongest broadside to the antenna. That's 'b' in your diagram. It decreases pretty slowly as you get off center, and will be noticably weaker off the ends ('A').

:adhering to the instructions. You will now become part of the Mail=20
:Order business. In this business your product is not solid and tangible, =
:
:it's a service. You=20
:are in the business of developing Mailing Lists. Many large=20
:corporations are happy to pay big bucks for quality lists. However,=20
:the money made from the
:mailing lists is secondary to the income which is made from people=20
:like you and me asking to be included in that list. Here are the 4 easy=20
:steps to success: STEP 1: Get 6 separate pieces of paper and write the=20
:following on each piece of paper "PLEASE PUT ME ON YOUR=20
:MAILING LIST." Now get 6 US $1.00 bills and place ONE inside=20
:EACH of the 6 pieces of paper so the bill will not be seen through the=20
:envelope (to prevent thievery). Next, place one paper in each of the 6=20
:envelopes and seal them. You should now have 6 sealed envelopes,=20
:each with a piece of paper stating the above phrase, your name and=20
:address, and a $1.00 bill. What you are doing is creating a service.=20
:THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate=20
:service and you are paying for it! Like most of us I was a little=20
:skeptical and a little worried about the legal aspects of it all. So I=20
:checked it out with the U.S. Post Office (1-800-725-2161) and they=20
:confirmed that it is indeed legal! Mail the 6 envelopes to the following =
:
:addresses:

:
:#1) Samantha Blizniak, 7937 S. Newcastle, Burbank, IL 60459
:
:#2)Katie Wiess, 14 White Tail Lane, Wallingford, CT 06492
:
:#3)Traci Wood, 4224 Carnwath Rd., Tallahassee, FL 32303
:
:
:#4)Milissa Crook, 3730 South 255th Place, Kent, WA 98032
:
:#5)James Buckner, 11903 Coit RD. #1803 Dallas, TX 75251
:
:#6)Bobbi Mullins, 31 Sunnydale Lane, Napoleon, OH 43545
:
:STEP 2: Now take the #1 name off the list that you see above, move=20
:the other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR=20
:Name as number 6 on the list. STEP 3: Change anything you need to,=20
:but try to keep this article as close to original as possible. Now, post =
:
:your amended article to at least 200 newsgroups. (I think there are=20
:close to 24,000 groups) All you need is 200, but remember, the more=20
:you post, the more money you make! This is perfectly legal! If you=20
:have any doubts, refer to Title 18 Sec. 1302 & 1341 of the Postal=20
:lottery laws. Keep a copy of these steps for yourself and, whenever=20
:you need money, you can use it again, and again. PLEASE
:REMEMBER that this program remains successful because of the=20
:honesty & integrity of the participants & by their carefully adhering to =
:
:the directions. Look at it this way. If you are of integrity, the =
:program=20
:will continue and the money that so many others have received will=20
:come your way. NOTE: You may want to retain every name and=20
:address sent to you, either on a computer or hard copy and keep the=20
:notes people send you. This VERIFIES that you are truly providing a=20
:service. (Also, it might be a good idea to wrap the $1 bill in dark =
:paper=20
:to reduce the risk of mail theft.) So, as each post is downloaded and =
:the=20
:directions carefully followed, six members will be reimbursed for their=20
:participation as a List Developer with one dollar each. Your name will=20
:move up the list geometrically so that when your name reaches the #1=20
:position you will be receiving thousands of dollars in CASH!!! What an=20
:opportunity for only $6.00 ($1.00 for each of the first six=20
:people listed above) Send it now, add your own name to the list and=20
:you're in business!=20
:---DIRECTIONS -----=20
:FOR HOW TO POST TO NEWSGROUPS----------=20
:Step 1) You do not need to re-type this entire letter to do your own=20
:posting. Simply put your cursor at the beginning of this letter and drag =
:

:your cursor to the bottom of this document, and select 'copy' from the=20
:edit menu. This will copy the entire letter into the computer's memory.
:Step 2) Open a blank 'notepad' file and place your cursor at the top of=20
:the blank page. From the 'edit' menu select 'paste'. This will paste a=20
:copy of the letter into notepad so that you can add your name to the
:list.=20
:Step 3) Save your new notepad file as a .txt file. If you want to do =
:your=20
:postings in different settings, you'll always have this file to go back =
:to.=20
:Step 4) Use Netscape or Internet explorer and try searching for various=20
:newsgroups (on-line forums, message boards, chat sites, discussions.)
:Step 5) Visit these message boards and post this article as a new=20
:message by highlighting the text of this letter and selecting paste from =
:
:the edit menu. Fill in the Subject, this will be the header that =
:everyone=20
:sees as they scroll through the list of postings in a particular group,
:click the post message button. You're done with your first one!
:Congratulations...THAT'S IT! All you have to do is jump to different=20
:newsgroups and post away, after you get the hang of it, it will take=20
:about 30 seconds for each newsgroup! **REMEMBER, THE MORE=20
:NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL=20
:MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** That's=20
:it! You will begin receiving money from around the world within days!=20
:You may eventually want to rent a P.O.Box due to the large amount of=20
:mail you will receive. If you wish to stay anonymous, you can invent a=20
:name to use, as long as the postman will deliver it. **JUST MAKE
:SURE ALL THE ADDRESSES ARE=20
:CORRECT.** Now the WHY part: Out of 200 postings, say I receive=20
:only 5 replies (a very low example). So then I made $5.00 with my
:name at #6 on the letter. Now, each of the 5 persons who just sent me=20
:$1.00 make the MINIMUM 200 postings, each with my name at #5=20
:and only 5 persons respond to each of the original 5, that is another=20
:$25.00 for me, now those 25 each make 200 MINIMUM posts with=20
:my name at #4 and only 5 replies each, I will bring in an additional=20
:$125.00! Now, those 125 persons turn around and post the MINIMUM=20
:200 with my name at #3 and only receive 5 replies each, I will make an=20
:additional $626.00! OK, now here is the fun part, each of those 625=20
:persons post a MINIMUM 200 letters with my name at #2 and they=20
:each only receive 5 replies, that just made me $3,125.00!!!=20
:Those 3,125 persons will all deliver this message to 200 newsgroups
:with my name at #1 and if still 5 persons per 200 newsgroups react I=20
:will receive $15,625,00! With an original investment of only $6.00!=20
:AMAZING! When your name is no longer on the list, you just take the=20
:latest posting in the newsgroups, and send out another $6.00 to names=20
:on the list, putting your name at number 6 again. And start posting=20
:again. The thing to remember is: do you realize that thousands of=20
:people all over the world are joining the internet and reading these
:articles everyday?, JUST LIKE YOU are now!! So, can you afford

:$6.00 and see if it really works?? I think so... People have said, "what
:if the plan is played out and no one sends you the money? So what!
:What are the chances of that happening when there are tons of new
:honest users and new honest people who are joining the internet and
:newsgroups everyday and are willing to give it a try? Estimates are at=20
:20,000 to 50,000 new users, every day, with thousands of those
:joining the actual internet.Remember, play FAIRLY and HONESTLY
:and this will really work

Message:

READING THIS=20
:COULD CHANGE YOUR LIFE! I found this
on a=20
:
bulletin board and decided to try =
:it. A=20
:little while back, I was browsing
through=20
:newsgroups, just like you are now, and came across an article =
:
similar to this that said you could make thousands =
:of dollars=20
:within
weeks with only an initial =
:investment=20
:of $6.00! So I thought, "Yeah

right, this=20
:must be a scam", but like most of us, I was curious, so I kept =
:
reading. Anyway, it said that you send $1.00 to =
:each of the 6=20
:names
and address stated in the =
:article. You=20
:then place your own name and
address in the=20
:bottom of the list at #6, and post the article in at least =
:
200 newsgroups. (There are thousands) No catch, =
:that was it.=20
:So after
thinking it over, and =
:talking to a=20
:few people first, I thought about trying
it.=20
:I figured: "what have I got to lose except 6 stamps and $6.00, right?"=20
:
Then I invested the measly $6.00. =
:Well GUESS=20
:WHAT!!...within 7
days, I started =
:getting=20
:money in the mail! I was shocked! I figured it
would end soon, but the money just kept coming in. In my first =
:week, I=20
:
made about $25.00. By the end of =
:the second=20
:week I had made a total
of over =
:$1,000.00! In=20
:the third week I had over $10,000.00 and it's still
growing. This is now my fourth week and I have made a total of =
:just=20
:
over $42,000.00 and it still =
:coming in=20
:rapidly. It's certainly worth
$6.00, & 6=20
:stamps, I have spent more than that on the lottery!! Let me =
:
tell you how
this works and=20
:most importantly, why it works....Also, make sure you
print a copy of this article NOW, so you can get =
:the=20

:information off of
it as you need =
:it. I=20
:promise you that if you follow the directions exactly,
that you will start making more money than you =
:thought=20
:possible by
doing something so =
:easy!=20
:Suggestion: Read this entire message
carefully! (print it out or download it.) Follow the simple =
:directions=20
:and
watch the money come in! It's =
:easy. It's=20
:legal. And, your investment is
only $6.00=20
:(Plus postage) IMPORTANT:
This is =
:not a=20
:rip-off; it is not indecent; it is not illegal; and it is virtually=20
:
no risk - it really works!!!! If =
:all of the=20
:following instructions are
adhered to, you=20
:will
receive extraordinary =
:dividends. PLEASE=20
:NOTE: Please follow these
directions EXACTLY,=20
:and $50,000 or more can be yours in 20 to 60
days. This program remains successful because of the honesty =
:and=20
:
integrity of the participants. =
:Please=20
:continue its success by carefully
adhering to=20
:the instructions. You will now become part of the Mail
Order business. In this business your product is =
:not solid and=20
:tangible,
it's a service. You=20
:
are in the business of developing =
:Mailing=20
:Lists. Many large
corporations =
:are happy to=20

:pay big bucks for quality lists. However,
the=20
:money made from the
mailing lists =
:is secondary=20
:to the income which is made from people
like=20
:you and me asking to be included in that list. Here are the 4 easy=20
:
steps to success: STEP 1: Get 6 =
:separate=20
:pieces of paper and write the
following on=20
:each piece of paper "PLEASE PUT ME ON YOUR
MAILING LIST." Now get 6 US $1.00 bills and place ONE inside=20
:
EACH of the 6 pieces of paper so =
:the bill=20
:will not be seen through the
envelope (to=20
:prevent thievery). Next, place one paper in each of the 6 =
:
envelopes and seal them. You should now have 6 =
:sealed=20
:envelopes,
each with a piece of =
:paper stating=20
:the above phrase, your name and
address, and=20
:a $1.00 bill. What you are doing is creating a service.
THIS IS ABSOLUTELY LEGAL! You are requesting a =
:legitimate=20
:
service and you are paying for =
:it! Like most=20
:of us I was a little
skeptical =
:and a little=20
:worried about the legal aspects of it all. So I
checked it out with the U.S. Post Office (1-800-725-2161) and =
:they=20
:
confirmed that it is indeed =
:legal! Mail the 6=20
:envelopes to the following
addresses:

#1) =
:Samantha Blizniak,=20
:7937 S. Newcastle, Burbank, IL 60459

#2)Katie Wiess, 14 White Tail Lane, Wallingford, CT=20
:06492

#3)Traci Wood, 4224 =
:Carnwath Rd.,=20
:Tallahassee, FL 32303

:

#4)Milissa Crook, 3730 South 255th =
:Place, Kent,=20
:WA 98032

#5)James Buckner, =
:11903 Coit RD.=20
:#1803 Dallas, TX 75251

:
#6)Bobbi Mullins, 31 Sunnydale Lane, Napoleon, OH =
:43545

STEP 2: Now take the #1 name off the list that you =
:see above,=20
:move
the other names up (6 =
:becomes 5, 5=20
:becomes 4, etc...) and add YOUR
Name as=20
:number 6 on the list. STEP 3: Change anything you need to, =
:
but try to keep this article as close to original =
:as possible.=20
:Now, post
your amended article to =
:at least=20
:200 newsgroups. (I think there are
close to=20
:24,000 groups) All you need is 200, but remember, the more =
:
you post, the more money you make! This is =
:perfectly legal! If=20
:you
have any doubts, refer to =
:Title 18 Sec.=20
:1302 & 1341 of the Postal
lottery laws.=20
:Keep a copy of these steps for yourself and, whenever
you need money, you can use it again, and again.=20
:PLEASE
REMEMBER that this program =
:remains=20
:successful because of the
honesty =

```
:&=20
:integrity of the participants & by their carefully adhering to=20
:
the directions. Look at it this =
:way. If you=20
:are of integrity, the program
will continue=20
:and the money that so many others have received will
come your way. NOTE: You may want to retain every name and=20
:
address sent to you, either on a =
:computer or=20
:hard copy and keep the
notes =
:people send you.=20
:This VERIFIES that you are truly providing a
service. (Also, it might be a good idea to wrap the $1 bill in =
:dark paper=20
:
to reduce the risk of mail =
:theft.) So, as=20
:each post is downloaded and the
directions=20
:carefully followed, six members will be reimbursed for their =
:
participation as a List Developer with one dollar =
:each. Your=20
:name will
move up the list =
:geometrically so=20
:that when your name reaches the #1
position=20
:you will be receiving thousands of dollars in CASH!!! What an =
:
opportunity for only $6.00 ($1.00 for each of the =
:first six=20
:
people listed above) Send it now, =
:add your=20
:own name to the list and
you're =
:in business!=20
:
---DIRECTIONS ----- =
:
FOR HOW TO POST TO NEWSGROUPS---------- =
:
Step 1) You do not need to re-type this entire =
:letter to do=20
:your own
```

```
posting. Simply put your =
:cursor at=20
:the beginning of this letter and drag
your=20
:cursor to the bottom of this document, and select 'copy' from the=20
:
edit menu. This will copy the =
:entire letter=20
:into the computer's memory.
Step =
:2) Open a=20
:blank 'notepad' file and place your cursor at the top of =
:
the blank page. From the 'edit' menu select =
:'paste'. This will=20
:paste a
copy of the letter into =
:notepad so=20
:that you can add your name to the
list.=20
:
Step 3) Save your new notepad =
:file as a .txt=20
:file. If you want to do your
postings in=20
:different settings, you'll always have this file to go back to. =
:
Step 4) Use Netscape or Internet explorer and try =
:searching=20
:for various
newsgroups (on-line =
:forums,=20
:message boards, chat sites, discussions.)
Step=20
:5) Visit these message boards and post this article as a new =
:
message by highlighting the text of this letter =
:and selecting=20
:paste from
the edit menu. Fill in =
:the=20
:Subject, this will be the header that everyone
sees as they scroll through the list of postings in a =
:particular=20
:group,
click the post message =
:button. You're=20
:done with your first one!
Congratulations...THAT'S IT! All you have to do is jump to =
:different=20
```

:
newsgroups and post away, after =
:you get the=20
:hang of it, it will take
about 30 =
:seconds for=20
:each newsgroup! **REMEMBER, THE MORE
NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL =
:
MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200** =
:That's=20
:
it! You will begin receiving =
:money from=20
:around the world within days!
You =
:may=20
:eventually want to rent a P.O.Box due to the large amount of =
:
mail you will receive. If you wish to stay =
:anonymous, you can=20
:invent a
name to use, as long as =
:the postman=20
:will deliver it. **JUST MAKE

>imbalance of currents.

Unbalance of current has nothing to do with noise pickup, unless you
are talking about feedline unbalance.

Noise, once it propageates a short distance, is exactly the same toi
the antenna as any other type of signal.

>It takes a very well engineered, large
>radial/counterpoise system for a monopole to approach the relative
>quietness of a dipole, let alone a closed loop.

What does a "closed loop" have to do with noise pickup?

Noise is an electromagnetic wave just like the signal from an
intentional transmitter. In close, within the nearfield and induction
foeld region, noise can be either electric or magnetic field dominant.

The reason a "dipole" is quiet is because noise, once it propagates
any distance along earth, has any horizontal components attenuated.
The same is true for any signal source, even intentional transmitters.
The dipole has two nulls, as well as poor response at low angles where
local noise comes from.

It is the pattern of the dipole that rejects noise, not the fact it is
balanced.

The same is true for the loop. It is the pattern of the loop that can
be used to reject noise, it has nothing to do with the fact it is
"closed".

A folded monopole is "closed", as is a folded dipole, and neither is
any different for noise pickup than the "unfolded" examples of each.
The exception is if the antenna is in incliment weatehr, and corona in
the antenna is involved.

>I have had all three up
>simultaneously, on an A/B/C switch, and my results have shown the
>typical, generally observed differences in received noise.

It isn't suprising the S/N is different. The antennas has different patterns. The one with the highest ratio of response in the direction and polarization of signal to response in direction and polarization of noise will always be the most quiet antenna.

>The most
>dramatic example of the effect of grounding on a monopole can be heard
>when using a random wire. With no ground, noise can easily rise above
>S9+. Connecting a ground, to a 8' CCS rod, will typically drop the noise
>by more than 20 dB.

That's because without a ground, the power line an house wiring and everything connected to them become part of the antenna system! The noisey wiring in the house become the counterpoise for the Marconi antenna.

It isn't because a "grounded antenna" is quieter, it's because you have eliminated or reduced common-mode coupling to the power lines!

>In dealing with nearby noise sources, like power lines, HV street lamps,
>and transformers, I have found that polarization of a receiving antenna
>is even more important than any directional characteristics of the
>antenna. Much of the noise-avoiding ability of yagis owes to their
>(usual) horizontal polarization, as it is a first principle of antenna
>theory and design that most manmade noise is *vertically* polarized.

Manmade noise is randomly polarized at the source. The fact is horizontal antennas have limited response along the horizon, and ground wave propagated horizontal components from noise sources are attenuated much more rapidly than vertically polarized components as they are propagated along the earth's suface.

It isn't because manmade noise is somehow magically vertically polarized, but rather how ALL signals propagate and how all antennas respond.

>The
>combined effects of polarization and a marginal counterpoise (which is
>typical, unless the ham has the space and takes the time to install a
>good one) make vertical monopoles the least desireable antennas in a
>noisy environment. The omni pattern of single verticals just makes
>things worse.

The "quietest" receiving antennas I have are arrays of short verticals.

The best receiving antenna in any environment depends on that environment. What works well in one place might be a "dog" at another.

Dipoles are just as susceptible as vertical monopoles to unwanted common mode currents. There is little difference between feeding a balanced dipole with an less than perfectly balanced line.... and feeding less than perfectly unbalanced monopole with an unbalanced line.

In either case the feedline choke will cure the problem.

The only thing that makes any antenna quieter than another, assuming you do nothing foolish in the installation and the noise source is not right next to the antenna, is the directional response of the antenna. You simply need a response null in the direction of noise that isn't also in the direction of the signal.

>Depth of wave penetration depends on wavelength, dielectric constant, >and conductivity. The soil behaves as a leaky capacitor.

Losses in the soil are complex, the soil acts like a large lossy media with phase shift. Visualizing the soil as a "leaky capacitor" paints a poor mental image of what really goes on.

>grows where.you live.

Dirt is dirt down here. Cars are vehicles. Pepsi and other soft drinks
are all called "Cokes". Down here, a smarty Yankee would be lynched
for asking for a glass of "pop". Now that we are past the local
dialects....

> With regard to the use of concrete laced with reinforcement as
>a suitable ground connection, swimming pools are the exception here
>so are not used to tie a tower legs to ground, concrete seems
>to be the next best thing. Certainly better than just a hole in the,
>how is it that you say it ....."dirt".

Unless the swimming pool has a LOT of rebar that is bonded together,
it would make a poor ground. Fresh water is a poor conductor, moist
concrete is no better than moist earth.

>As concrete retains moisture its use has even more going for it

It retains moisture, but doesn't have anything special going for it
other than that.

I found some scholarly technical papers on the Web, and the only part
of concrete that "conducts" is the paste between the very poorly
conducting fill in the concrete. It has to be treated as a somewhat
resistive paste filled with non-conductive objects.

>With respect to voltage levels used for testing purposes, there
>is many an engineer out there that state, in error, that an electrical
>contact is mechanically open when using a Simpson
>that uses" low " (battery) voltage levels to test continuity

The statements made I questioned were:

>The NEC doesn't require that. But the Ufer will be there because it is the
>best practical lightning ground you can create.

That appears to be incorrect. Polyphasor as well as other sources say
a Ufer ground is not enough.

>The old wives' tales about exploding concrete are just that, old wives'
>tales.

Concrete can explode, if the ground system is poor or the path is through a small area of concrete. It won't with a proper grounding system, but the tales of concrete exploding are not necessarily all "old wive's tales".

>The reason this works is that concrete is a better conductor than >average dirt, so it spreads the strike current from the rebar more >effectively than can the ordinary dirt around a driven rod.

We still have no data to support that. Everything I can find says concrete, at very low frequencies is a "poor conductor". I compared a driven rod to a "poured in concrete rod" the same length. At least I did SOMETHING, other than pontificate.

If concrete was that good of a conductor, I would assume using the exact same test method it would indicate at least a somehwhat comparible resistance to dirt.

I did find a test on the Towertalk reflector someone did in 1997, where the base fed a tower set in concrete and found little impedance difference from an insulated tower worked against a radial system, not that that means much.

So what I'm looking for are resistivity numbers. The only things I can find indicate concrete varies widely in resistivity depending on the ratio of paste to non-conductive rock fillers and isn't all that good compared to dirt with the same moisture content.

.....and you are all being trolled by the master troll.

Anyone with any background in antennas, operating, and propagation should know none of this has anything to do with how an antenna works, let along the advantages or disadvantages of one loading method over another.

It's all just a bunch of male hormone driven bar-room weenie wagging.

People fall back on this "I worked XX with my YY so it must be superior" crap when they have no technical arguments.

Chip can turn any technical discussion to a personal pissing contest because he is able toi sucessfully troll you fellows.

He has admitted his tiny-tot antenna only has 3 dBd or less gain. Big deal.

3057. Glass Mount Installation Help

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-24 00:00:00 UTC
From: "G. M. Privette" <jmpl@mediaone.net>
Message-ID: <ltmz5.88496$56.415193@typhoon.jacksonville.mediaone.net>
Source record: 179779

I purchased a Valor/Pro-Am 2m/70cm Glass Mount Antenna (new). No
installation instructions included. My questions are:

1. How to orient the inside base? Can it be mounted in any orientation,
i.e. the coax connector pointing down, left or right?

2. How to orient the ground plane wire that is connected to the coax
connector? Can it point away from or toward the inside unit?

I read the installation instructions for the MFJ version of this antenna and
they say to orient the inside base with the coax connector pointing down.
The instruction for mounting the ground plane wire is confusing.

Any help and experiences with this antenna are appreciated.

Thanks,

Jerry, W4JX

Or more. I was being conservative, for that F/B and SWR.

> Big
>deal.

Perhaps you can suggest a simple, high performance alternative that matches the performance and maintains the ease of construction, reliability, and so on. I will even suggest one for you: an H element. Try it and see. I did.

The FQY element
(See, for example,

.
http://www.fractenna.com/ham/hampage1.html)

is made from a single piece of wire, easily bent, constructed, and used. I have had mine up for 26 months WITHOUT REPAIR TO THE ANTENNA. It has withstood several Ice storms; a tornado; and countless no'reasters.

As a fractal element, it is part of the set of SHAPED ANTENNAE elements -- first pioneered by Landstorfer in 1976.

SHAPED ELEMENTS include: fractal antennas; genetic antennas (so-called); and knot elements. Much of the analytics of such antennas , except in specific or simple cases, is impossible to solve amd no closed form solutions have been articulated by Landstorfer or Cohen or Linden or Werner or anyone else.

Instead numerical solutions are EXPLORED.

Instead, for optimization purposes, one cannot take various derivatives and use standard optimization approaches.

Instead, for optimzation purposes, TOTALLY NUMERICAL engines are used which , in fact, do not in any way utilize the knowledge base of individuals, other than to set boundary conditions and articulate a figure of merit in the design. The fact is that your criticize of me also applies to the earlier use of this approach by Landstorfer and Sacher; and extends in criticism to such active users as: Haupt; Werner; Hohlfeld: Altschuler; Ramat-Samii; Werner; Linden; Mittra; and literally hundreds of other researchers and students.

Now: you may object to said approaches. That's OK. You may buck the extant frontiers of electromagnetics. {For a description of fractal antennas, knot antenna, and genetic antenna optimizations, see FRONTIERS IN ELECTROMAGNETICS(Werner and Mittra, IEEE Press,2000; Landstorfer's work is summaried in OPTIMIZATION OF WIRE ANTENNAS by Landstorfer and Sacher, Interscience, 1985).

What you CANNOT do is focus on me, as an individual, and vent your frustrations with it by personally attacking me, and even doing a death threat.

As an RF contractor for MFJ/ Enterprises (which include Hy Gain Antennas) it is of little consequence to you how these 'new' aspects of antenna design are done. However, you must realize that by personally attacking me, you also represent your affiliates, as,indeed, I do.

All this information I have posted on this NG, some many times. It is also readily accessible to anyone who undertakes literature searches.

So go ahead and say anything you want--TECHNICALLY. I do not feel oblifgated to correct you when you are wrong (which is often, as here).

But keep the personal attacks off the NG.

And watch the difference.

George,

"Need" is a relative term. My Butternut vertical worked just fine without radials--enough to achieve DXCC anyway. Granted that the ground is a little on the moist side in Northern Illinois. And like I said, the efficiency is compromised. And the original question referred to having zero space anyway. to me that means no room for any radials.

The use of sixty radials is a throwback to broadcast station practice and certainly not necessary in amateur practice. The Butternut radial kit only has four of them. What difference do you belive might be heard on the receiving end of your transmissions by going from a few radials to 60?

Mike Donnelly

Yes, Sarah was able to compete her project with very little if any of
your help. I know Sarah and her Dad very well they are members of the
local radio club of which I'm a member...

When I read you post I checked with her father as to your corsponding
with him on Sarah's project. Here's his reply to my query

"No Chip didn't really provide Sara with any info, other that the
minimal stuff available on his web site. He did send an e-mail after
he heard about her project (before the state science fair), but never
responded to her reply. He doesn't seem all that interested in
sharing info with much ofanyone."

Your implying that you *helped* is disgraceful.

Danny

Excuse me;

I NEVER, EVER received ANY CORRESPONDENCE of ANY KIND from Sara. Nor do I in ANY WAY claim to have helped her.

She did this on her own.

I e-mailed her dad congratulating her. He wrote back detailing some of her work. Your assertion that I did not help her (when asked) is an abomination.

>Lawrenceville, GA | Guaranteed |

Don't forget that the main benefit of log periodic antennas is their
wide bandwidth, not high gain.

In the USA, with the relatively large number of off-air VHF TV channels
available, the ultra-wideband type of antenna (lowband, highband, and
even UHF) is very common, but I doubt if the gain is much more than 3dB
or 4dB (please correct me if I'm wrong). You rarely see this type of
antenna in the in Europe, and even less so in the UK (we don't use VHF
for TV any more!).

The US TV channel is not really 6MHz wide - this is the spacing between
adjacent channels. It is really about 4.5 + 0.75 + 0.05 = 5.4MHz
(allowing for the vision-sound spacing + VSB + USB of FM sound
deviation). I would have thought that you could buy high-gain, single-
channel yagis specially designed for single-channel fringe area
reception (say 4 or 5 elements, or even more). However, I know that
'higher-gain, narrower-bandwidth' (by log-periodic standards) log-
periodics do exist (or can be made).

I don't doubt your abilities but, if you are more interested in getting good TV reception rather than experimenting with antenna construction, it might be better to get an antenna (with a good reputiation, of course) off the shelf.

Ian.

OK. In that case having a blunt conductor, and some form of DC
leakage to earth, will reduce noise. But that isn't loop specific.

The original post was talking about power line noise.

John,
Can't say much about using radials with the 10' height
requirement,
but as to the wind problem, guy the antenna. May have to use guy's on
multiple levels, but that should be no problem. It's always better to
'over-do' than to 're-do'...

3074. FRACTAL QUAD YAGI--HITTING RECORD QSO RATES

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-24 00:00:00 UTC
From: fractenna@aol.com
Message-ID: <20000924111259.21759.00000501@ng-cc1.aol.com>
Source record: 179796

This weekend, in just a few hours of operation, I acheived record QSO rates (for me) with the 10M Fractal Quad Yagi seen on:

http://www.fractenna.com/ham/hampage1.html

which details the outstanding performance characteristics and ease of construction. The antenna also appeared in (articles by other authors in) La Revisita, QTC, and 73 magazines and elsewhere.

My rate never dropped below 130Q/hr. For one 1/2 hour stretch it acheived 335 Q/hr. On average it was 195 Q/hr.

At least 2 dozen times I received unsolicited comments which stated I was the strongest W on the band.

This is with a JST 245 on 10M phone.

I am now using a voice keyer, although I find that it is a real turn off to most CQ's, because it sounds so...unanimated.

July 5, 1999. F1 Tornado.

It was witnessed, here, by 4 people. Damage included snapping a 14 inch oak tree and a 12 inch maple like tooth picks, at the 10-15 foot level.

It skimmed the area over a 3 mile swatch over Lexington, Arlmont, and Belmont.

I described this back on the NG some time back.

This is a very serious claim. I will call Sara's father this afternoon. If he wishes, I will let him call my associate dean to discuss the issue.

I never had any contact from Sara. Ever. The contact was from me to her dad--congratulating her on Sara's previous (pre CS Sci fair) progress.

My policy regarding students is this: I am happy to help, but they need a faculty (or teacher)supervisor to e-mail me,stating the nature of the project and the person who will oversee the student. This prevents the temptation some students have of mis-using info provided, particlularly 'net info.

Plagiarism is rampant in higher education and the 'net is too easy for students to abuse.

An example of where I have aided a student (one of many) who proceeded in this way is:

http://www.eee.bham.ac.uk/com_gr/petersong/kochdipoles.htm

this is a student at the University of Birmingham , who did a very nice job.

My first obligation is to my students at my home intitution, but I am always happy to help for those who abide by my reasonable request. I must admit that I am astounded how many students do NOT proceed based on my request that they have a teacher drop me a line.

Hope this helps.

Nathan Cohen, Ph.D.

Lord Kelvin was a fine physicist, but not omniscient. He was
able to express the age of the earth in a number, but that didn't
mean he understood geology. His number was, unfortunately, wrong.

Here's another thought:
Take your antenna and analyzer to a park or beach or parking lot -
anywhere where you can mount it in the clear for at least 20 feet
horizontally and at least 5 feet or higher above ground. Connect the
analyzer to the antenna with 20 feet of rg 58 and tune it for lowest
SWR. You need to be able to get to 1.2 to 1 or below. Then, add
a coax jumper about 3' long between the 20' coak and the analyzer.
If your SWR stays low, your antenna is in good shape. If you can't
get a low SWR, there's something wrong with the antenna, coax, or
analyzer.

I believe your 1:8 to 1 SWR is not due to its height - I suspect it is
due to being near the structure and balcony.

You might be able to make use of the building layout to install a 2
element outdoor beam! If the balcony above is about 10 feet wide,
you could mount a reflector on the face of the building. 3 feet
or more out from the building and in the same horizontal plane
of the reflector, install a pair of aluminum tubes separated by
about 2 - 3 inches. These will make a dipole. If you mount this
stuff sturdily, you can hang birdfeeders off the ends with fishing
line. Surely they'll allow birdfeeders! Now that "justifies" the
construction - all you need to do is feed it with coax and a
5 turn coil of #14. Use a broom handle as the coil form - you
spread or compress the turns to achieve resonance where
you want it. The coil goes in series with one element and the
center conductor of the coax. Hide all that junk - the coax
and coil - with the center support attached to the balcony
above. If you are clever and there is some latitude to allow
you to install this "birdfeeder" I think you can get away with it.
If you need exact dimensions, let me know - I'll go measure
the dipole I made with copper pipe that way. The elements
were cut a bit short - 48" if I remember.

By the way - "model" this antenna in that open space mentioned
earlier. You'll have to "Rube Goldberg" it a little - but with 6 meters
and above, it is easy enough to bring the pieces you need with you
and experiment in the open.

My thinking in this is as follows: basically, what you have now
is a unidirectional antenna, with some of the power wasted AND
creating a higher SWR. Make use of that by intentionally reflecting
the power and tuning the antenna for the change in impedance that
the reflected power causes. The reflector itself is easy to hide, as
it is mounted directly on the building. It can even be incorporated

as part of the support for the "birdfeeder". You already have the
problem of hiding the driven element with your two fiberglass whips,
so that problem exists whether we're talking beam or just dipole.

Finally, the driven element might be more hideable using a hairpin
match instead of a coil. You could even hairpin match the reflector!
To do that, you would first adjust the driven element without the
reflector installed. Then. install the reflector (two elements, just like
the driven element but a little longer, connected together by the hairpin)
and adjust the reflector hair pin for lowest SWR as measured at the
driven element feedpoint. Note that I have tried this in open air and
it works - but I've never tried either method with the reflector mounted
directly on the surface of the building. But it sure seems worth a try!

Actually 50.15 MHz is the center freq. This is ssb. Yes I have tuned the
stingers quite a bit to get it to this point.

The only metal would be nails used to put the deck together. There is a small
satellite dish for television on the deck above mine, but I don't think that
would make any difference. I really can't move the antenna away from there
anyway.

The most simple model of soil, rock, or what have you, is a capacitance in parallel a resistance. If you've ever heard about such clever, academic, mind-boggling things as complex dielectric constants, forget 'em.

Its much more simple than that.

Soil resistivity R is that which would be measured between opposite faces of of a 1 metre cube of the material.

The capacitance is that which would be measured between the opposite faces when the dielectric constant of the material is K, air being unity.

The capacitance is 8.85 * K picofarads. The reactance of this capacitance is in the same units as the resistance - it is in ohm.metres.

K can be anywhere between 3 and 80, typically concentrated between 9 and 15

A better wide-band model is C in parallel with R, both in parallel with another R and C in series. The R's and C's are proportioned according to the size of the solid particles in the soil relative to the remaining space occupied by moisture. Water has very high dielectric constant K = 80 and so the effective dielectric of a soil, as is its resistivity, is closely dependent on the distribution of particle size and shape and its moisture content. Arid soils, rocks and sand, are insulators with K around 3 to 5. Moist soils containing natural fertilising salts have R from 25 to 70, and K from 30 to 15

To understand more easily how this affects ground loss, ground reflections, ground propagation, etc., it is better to view a soil sample as an impedance, R+jX, where both R and X decrease with frequency. Impedance and ohms are quantities we are all familiar with. I have to stand on my head while performing a mental division before grasping the meaning of a number of milli-Siemens.

To investigate what happens in your back yard there is no alternative to making measurements on site. FCC curves will tell you no more than what can be deduced by running the soil through your fingers. Attempting to make precision measurements is a waste of time. Attach 20 or 30 percent or more to measurement uncertainties. Ignore HP, GR and W&G

claims. Banish all delusions of accuracy to the the
recycling bin.

But for most people it is sufficient to know only whether
the soil is good, bad or indifferent when a computer program
asks for ground information. With a good set of radials the
soil condition has only a minor effect on the performance of
a ground-mounted vertical antenna. And an even smaller
effect on a well elevated array. Other environmental
factors such as the presence of feedline, towers, buildings,
building contents, forests, overhead wires and a bus parked
across the road result in greater uncertainties.

Thanks to everyone that answered so quickly. I am going to try a wire dipole and then maybe a loop and see what happens. Part of my concern of the 'high' SWR as this is only a 10 watt rig and if much of the signal is lost at such a low height...well..... Thanks again for all of the good and (I must add polite) speedy answers.

3099. Re: Power lines: how far is far enough

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-24 00:00:00 UTC
From: Will <gwelfster@earthlink.net>
Message-ID: <39CDBE6B.D4DC6555@earthlink.net>
Source record: 179864
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx,rec.radio.amateur.misc

Unsure precisely what "gender" might mean as applied to an antenna, but guessing it may have something to do with design, I say such characteristics have a large impact on how much noise an antenna picks up. Monopoles are prone to be among the noisier antennas due to imbalance of currents. It takes a very well engineered, large radial/counterpoise system for a monopole to approach the relative quietness of a dipole, let alone a closed loop. I have had all three up simultaneously, on an A/B/C switch, and my results have shown the typical, generally observed differences in received noise. The most dramatic example of the effect of grounding on a monopole can be heard when using a random wire. With no ground, noise can easily rise above S9+. Connecting a ground, to a 8' CCS rod, will typically drop the noise by more than 20 dB.

In dealing with nearby noise sources, like power lines, HV street lamps, and transformers, I have found that polarization of a receiving antenna is even more important than any directional characteristics of the antenna. Much of the noise-avoiding ability of yagis owes to their (usual) horizontal polarization, as it is a first principle of antenna theory and design that most manmade noise is *vertically* polarized. The combined effects of polarization and a marginal counterpoise (which is typical, unless the ham has the space and takes the time to install a good one) make vertical monopoles the least desireable antennas in a noisy environment. The omni pattern of single verticals just makes things worse.

3101. Re: Antenna Question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-24 00:00:00 UTC
From: Will <gwelfster@earthlink.net>
Message-ID: <39CDC174.F90D7EC2@earthlink.net>
Source record: 179866

For what you would spend for the B&W folded-dipole, you can easily pick up a 300W roller-type tuner. Add a spool of wire, and you have an antenna that almost certainly will outperform the B&W, on most frequencies/bands. If one wire configuration doesn't work, or your needs and preferences change, a few dollars of wire gets you an entirely new antenna, using the tuner. Unless they are very badly abused, tuners last almost a lifetime. The little MFJ "random wire" tuner (model 16010 I believe) is inadequate for more than QRP transmitting levels, and in fact is marketed as an SWL antenna. The 941, or even better the 969, offer you *much* safer power handling and matching range. You can pick one up used for about 60-75% of what these sell for new. Several sellers advertise both models for significantly less than you can get them from MFJ direct, as well. You might invest in a used recent copy of the ARRL antenna handbook also, for a solid and thorough introduction to all aspects of antenna design, installation, and use.

I am unclear whether you have made any adjustments to the "stingers" on the ends of your two fiberglass whips? If not, you might try shortening and lengthening them, and checking the results progressively on the analyzer. Shortening the elements will generally cause the resonant point to go up in frequency (which I think is what you want, since you quote measurements for 50 MHz, which I doubt is the *center* frequency you have in mind.), and vice-versa. You might also check the area near where the antenna is hidden for pieces of metal--flashing, conduits, pipes, etc. that may be in effect de-tuning the antenna. If you find something like this, move the antenna if you can. Be sure as well that the antenna is put together correctly and is in good condition--i.e. no shorts or opens in the feedline or around the feedpoint especially. If none of this works, it is pretty easy to fashion a closed fullwave loop for 6-meters, and such an antenna is easily hidden in a location such as yours, since it is only about 5 feet on a side, and made of wire.

Hi this is Jon again, the guy who made the original post. This last comment seems to tell me that even using a long wire up high, with an antenna tuner is a better alternative than the B&W antenna. Am I understanding you correctly? One reason I was looking at the B&W was that a friend was going to let me use his. That is part of the reason I said I was trying to watch my pennies. I am on disability so money is scarce here. What about a long wire and the inexpensive tuner that MFJ has for a random length wire antenna? I do understand that most of you have said go di-pole, and I probably will include that also. No one has told me if these type of antennas are directional or omni directional. Thanks for your continuing input; I appreciate it all! Jon.

>
Been there, done it gazillions of times under very similar condx. No different than
going to LA or Chicago on biz for two days, the job gets done and nobody dies.
Including the dog. If you had any real interest in doing the 'test at somebody
else's qth you'd work it out.
>

>
> I wasn't referring to brutal in an admirable sense.

I was. It's the esssence of competition. You think maybe football players take
turns and say "'scuse me!" when they pile all over a runner already??
>

> What I mean is that Yuri
> breaks laws by stomping on others (malicious interference; grabbing frequencies
> already being used);

>
(a) Nobody guaranteed anybody a "clear freq". (b) Stomping has been SOP since the
first ham contest whenever that was. If ya can't hold yer freq get a bigger antenna
and/or radio or move up the band and ragchew. Like I sed, not for the thin-skinned,
inept or whiners.
>

> not properly ID'ing; and so on.

>
If he didn't ID the other stations wouldn't know his call and the q wouldn't get in
the logs. Lotsa contesters don't spit out their calls during every contact when
they're running and the FCC has known that since whenever. To the best of my
knowledge nobody has ever been spanked by the feds for this minor SOP infraction.
I'm sure you've done 60 in 55mph zones and never got busted. The FCC doesn't have
time to be anal, all they care abt is being able to identify the station when he
does send his call.
>>

> >Running EUs on 80 & 75 is even more fun. Except ya need real ears and

>
Sorry to hear that, I wish you well.
>
The least expensive and biggest bang for the buck route by far is single-band
dipoles. Three insulators, some Home Depot #14 stranded THHN general-purpose wire,
some 8X coax, a PL-259 connector, some rope drapped thru some trees and bingo,
you're very efficiently on the air on any single band of your choice with a decent
swr for maybe $50 at most with all new "stuff", more like $30 if you shop around,
and for $5 per band if you really scrounge around. No tuner required at all.
>
>What about a long wire and the

> inexpensive tuner that MFJ has for a random length wire antenna?

>
I'm a bit suspicious about the ability of the little $50 MFJ-16010 guy to have
enough flexibility/tuning range required to cover the widely varying feedpoint
impedances you always run into with random end-fed wires. I could be wrong. Another
$30 for the 901B is probably a much better choice. I have both the much more
expensive 969 and the 941E tuners and both will match and load anything in sight
which even vaguely looks like it might radiate RF.
>
Keep in mind that the primary money tradeoff here is the cost of multiple
single-band dipoles without the need for any tuner and one all-band wire plus it's
tuner. The secondary tradeoff is the availability of antenna supports, hanging some
number of dipoles spaced apart so that interactions are not a problem vs. hanging
one wire, etc.

>
From the dollars and sense standpoint you'd probably come out ahead by picking two heavily-used bands for starters, say 20 & 40m and go with two dipoles IF you'll be happy with only two bands. If you want to run all nine of the ham bands which are below 30Mhz you'd be much better off with one duz-it-all wire plus it's $$ decent tuner. Plus you'd have to learn how to use the tuner. Which, when mastered, has it's own side benefits like amazing your friends who think that the planet spins around 50 ohm feedpoints.
>
Also keep in mind that if you go with a wire you should also string a counterpoise around the grounds of the estate.
>

> I do understand that most of you have said go di-pole, and I probably will
> include
> that also. No one has told me if these type of antennas are directional or omni
> directional. Thanks for your continuing input; I appreciate it all! Jon.

>
The classic dipole in isotropic space operated on it's fundamental freq has lobes broadside to the wires. If operated on other freqs the H-Plane lobes go every which way as shown in the ARRL Antenna Book. Random wires behave in a more or less similar manner. Fact is that no such thing as isotropic space or "classic dipoles" exist. Real-world pattern predictions for any backyard wire antennas are pointless exercises in futility because of the huge volume of uncontrollable variables. Ya takes the patterns ya gets, just put it up, get it on the air and enjoy HF ham radio.

I used a Gap Titan for about a year and *thought* it was great. Pretty weak on 80 but works the rest of the bands.

Then I got a 2 element Quagi from TGM in Canada and found out that I had made a big mistake with the GAP. The Quagi is not much bigger than a TV antenna, uses a cheap Radio Hovel TV rotor and works 20 - 6 mtrs. It is at least 2 S units better than the GAP has good directivity and is a much -- much better antenna for the money.

If you have to compromise, look at the Quagi and put up some kind of dipole / long wire for the lower bands. At this point in the sunspot cycle, all the action is on 20 and above anyway.

Sorry - the Butternut vertical DOES need radials. I operate mine over 60
radials buried about an inch. Butternut makes it clear that their
verticals do not work without a radial system.

And mine is "very efficient."

3112. new antenna help (using MFJ analyzer)

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-24 05:02:06 UTC
From: sideband@mindspring.com
Message-ID: <39CD8ACE.7E0F8DFF@mindspring.com>
Source record: 179855

I have a MFJ 9406 (6 M) SSB radio and a dipole antenna. I also have the use of a MFJ 259 analyzer. The dipole is a metal bracket that allows 2 fiberglass whips to be attached to it, both with ends that allow them to be tuned. I am only able to put this antenna about 8 feet in the air as I live in a 'no antenna' apt. complex and currently have it hidden under the wooden balcony of the apartment above me. The SWR is currently about 1.8 at 50 MHz. If I tune the frequency either up or down on the analyzer the SWR goes up. Does this mean that the antenna is tuned as good as is 'possible' and the high SWR is because of the location or will more diligent work in tuning help? I think this is just because of the low height but I defer to those more knowledgeable. :-) Also, can you think of anything that will help to lower this SWR? Grounding something? Standing on my head in a bucket of water? :-) I have not been able to even hear anything on the radio yet let alone make any contacts and wonder if this is part of my problem. I know the location and height are not ideal but it is what I have to work with. I can get lower SWR in the apartment but every time I key the mic I come blasting through my pc speakers and stereo (even though it is turned off).

One last thing. If this is the antenna:

```
b
A ---------------------{}---------------------- A
b
```

Which directions are forward and back? A or B?
Does that make sense?

Thanks a lot
Joe

Source record: 179856

Hey Joe,

This might be a tough problem. Given the data,
I would guess that the twin-whip idea has gone
as far as it can. The fact that the SWR goes up
when you vary the frequency in EITHER direction
indicates that the antenna is tuned about as well
as it can be.

It might be affected by metal (such as electrical
wires and structural elements) in the walls.

One thing to try would be a wire dipole in the same
location. If the wire dipole acted the same as the
whip antenna, then you have a problem.

It's interesting to notice that the rig gets into
the speakers and such. This indicates that
RF is being generated, and that the rig
is loading up OK. But... this is also going
to be a problem...

Direction "B" is the most often considered when
looking at directivity of dipoles. Little radiation
occurs off the ends of the dipole.

But remember that this is only true if the antenna
is at least a wavelength high and in the clear.

Good Luck!

Source record: 179858

Joe,
It sounds like the 1.8:1 is as low as it's going to get as the antenna is adjusted now. Changing the 'stinger' lengths my drop it down some, but I think you've got the lowest SWR your going to get. Changing height my have a 'good' affect, but maybe not.
I have no idea why your not hearing stations on 6 meters. I don't work 6, so can't say, but it seems like you should hear someone.
The reason your hearing your self in the stereo speakers is over-load. The speaker wires may be just the right/wrong length and acting as an antenna. You can try by-passing the speaker wires, use torroids, etc, on them but I don't think it's going to do much good. You've just got a ~lot~ of RF in the shack.(One of the problems with an indoor antenna.)
If I understand your question about the antenna, the major direction of radiation would be perpendicular to the elements of the antenna (B-B). Since the antenna isn't very high (1/2 wave above ground), it probably has more of an omni-directional pattern that's distorted in 'whatever' direction because of it being inside.
Good luck with it...
'Doc

Janice,
I don't know if anyone can answer that question. It depends
on how and where each antenna is erected. What's around it, how
high it is, how well tuned, etc. There probably isn't all that
much difference...

I'm looking into verticals that work on an 8 story building? It'll be about 120" up and with a contast wind. I live in brooklyn, NY about 2 blocks from the water (NY Bay).
I see that the ants. are a big tall, so I'm worried about wind since most look like multiple sections. And if the antenna has radials, those would have to be at least 10 feet off the roof (Fire code). I have an old Shakespeare Big Stick CB antenna that I have been using on 10m and the top half on that bends a lot and quite often I see the top section doing a 90 degree bend

ANy help would be appreciated.

Hi,
How would you like to make some money immediately? Check this site out- :
http://www.ineedthat.tv/signup.php3?r=AAKLEZ&MemberID=NEW

I guess there's a glitch in the system that the company knows about, but
they
haven't fixed as yet. Here's how it works. Sign up, then go back in and
login. After all this click on HOME. On the right you will see where it says
"Tell me more about keywords" click that. Scroll down and click NEXT. Scroll
down on the bottomhalf and click the white and red logo box. Then a small
box
should pop up with your user name in it. Whiteout where it says enter
keyword
and type GOLF. Click go. This is where the glitch is. Basically you can keep
getting paid for this keyword. I was told to hit the backspace on my
keyboard. You don't have to close the wimndow, just keep going back to the
main screen and click the red and white logo box again. It will renew the
smaller screen again, and you can type GOLF as the keyword again. Try it
about 10 times, then go back to the main page and check your stats. It
should
show how many times you did this and you get paid $.25 for each time.

This is a letter my upline got from her cousin.
Hey everyone,
Guess What?? My friends that told me about the Ineedthat tv said he called
the CEO!!! He said that the company knows there's a glitch and they are
fixing it, but they don't really care, and they said they send the checks
out
on the 15th. They said it was their lawyers fault because they knew the page
wasn't ready but the lawyers made them put it up because they told all the
web companies that it would be up by a certain date. So maybe if we all hold
our breath together. OH! OH! he said that a lot of people knew about this
and
there were some people who didn't even get referrals, they just racked like

$10,000.00 under their own names!
Anyways,
Talk to you all later,
Danielle.

You may want to hurry up and sign up before they fix the glitch. Tell all your friends.

Jassodra.

As one who is in the squirt gun category in contests (QRP at <20 dBm ERP in the CW SS), I can attest to this. If someone appears to be a sharp op, I will wait out the pileup until I get through; if he or she is efficient, there will be an opening sooner rather than later. If the op is fumbling around at all, I move on to the next op, hoping to maybe come back later. The first one will get me more often than the second one.

Now, speaking of contests, Chip, you were looking for a challenge. Would you care to take me on for points per watt in the 2000 ARRL CW Sweepstakes? I won't call you a chicken if you prefer a different type of operating and don't accept. :-)

I want to put up a wire 20 m dipole for qrp cw. I have a 2 story house.
Which would be the better of these 2 options:
1) a dipole strung from the edge of the roof (16 ft high) to a 16 ft pole at
the edge of the property or
1) an inverted v strung across the top of the house supported in the center
at 8 ft above the roof and sloping down at each end to a few inches above
the roof.

In the case of the inverted V, the coax feed line would be about 60 feet ,
and with the first option, the feed line would be about 90 feet. (Should I
be concerned about this?)
Tnx

>I, too, will come out of the closet. :-)<

Me too, Ed! I once supervised a University AV Center where we fixed all kinds of broken TV monitors and receivers (Remember all the SAMS PhotoFacts and crappy Sencore test equipment?). Then I was a TV systems designer and also built editing systems and classroom dispaly systems. Later, I was a TV Writer/Producer and a (yuck) Video Editor. I've even worked as "Talent" (using the term very loosely). Near the end, just before I hit rock bottom, I did Distance Learning Centers--peddling my wares to....kids.

I'm better now, but occassionally, when I watch the news at bedtime, I sneak into the remote menu and change a setting or two----just to see if I've still got it.

What's most distressing, though, is that my kid has a IMAC ITV and a DVD camera. I'm afraid, like Fetal Alcohol Syndrome, these things may pass from generation to generation. "Promise me son, not to do what I've done!"

Maybe better if this would be higher than 16 ft. Just watch out for
wiring etc under the roof. Can couple with antennas and make tuning
tricky. Being the apex would be 8 ft above the roof I don't think you
would have problems. I think I like this 2nd one better. Should be over
20 ft up. Better than 16 ft..You might look into lightning protection
for that antenna. Dipoles generally don't get hit very often, but you
don't want to take chances. I'd either connect the coax to ground
outside during storms, or use a suppressor of some type, to at least
keep from burning the shack down in case of a strike.

Vertical sweep tube shot, and yoke got twisted 45 degrees.

Sure glad I got out of that business before anybody found out how little I know about it!

Actually, I found TV repair to be much more challenging than military heavy ground radar repair, which I've also done. The TV circuitry was extremely obtuse, with every trick imaginable to take a nickel out of the production cost. And the components were crappy. You'll probably never see an open circuited capacitor in any kind of quality equipment, but the ones they used in TVs commonly had an end cap come loose internally. One episode I remember is a problem with the sync. It turned out to be caused by a tired video output tube. The designer needed 25 or so volts of DC to bias something in the sync circuit, and got it from the video output stage cathode resistor. The video output tube's current was off -- not enough to bother the video, but enough to goof up the sync bias. Another one I saw with me own eyes was a car radio which wouldn't work due to the car battery being connected backward! Yes, the car started, and ran. The gauges didn't work. That was back in the generator days -- the car was a Corvair, mid-60's. I also recently came across someone else who saw the same thing.

Anyway, my hat's off to those of you who make your living this way. It isn't easy, and the pay's not that good. You have my respect.

Hi Tom,

The discussion of the classics would probably come to a more
satisfying conclusion than having to live them by mutated proxy within
this group.

My choice for a better depiction of Roland (Orlando) would be "La
Chanson de Roland." (It is consistent with the sacrifices made.)

Well, since we are all confessing...

I did TV repair during high school and aircraft radio repair during college.

FWIW, when we were hiring engineers, we looked more favorably on someone
with a C to B average that worked as a technician of some sort than we did
on someone with As and no tech experience.

All the best engineers I ever worked with had tech experience.

The TV set has a defective deflection yoke, or circuit problem,
allowing the horizontal and vertical deflection windings to be driven
with the same sweep signal.

Of course from a do-it-yourselfer, you could find no vertical sweep
and a twisted yoke.

Now for an amateur related question.

What TV sweep tube was the most powerful sweep tube ever used (hint,
Admiral TV's only), capable of over 200 watts output on CW with
excellent tube life?

Source record: 179483

I'm very, very sorry to hear this.

For several years, I've watched one person after another appear on the newsgroup and try to engage Chip in a meaningful technical discussion. And one by one, they fall under his onslaught of insults, arrogance, pedantry, rudeness, and childish behavior. No one has succeeded. No one will succeed. For a long, long, time, I bit my tongue hard, and tried really, really, hard to treat Chip the same way as I try to treat everyone else. I bent over backward to not say anything insulting or personal. My comments were directed solely to what was said, not who said it. I'm far from perfect, so I didn't always succeed, but I think I did pretty well. But I finally lost it after asking a series of honest and objective questions, and getting the usual rude smart-ass one-liners and insults in response. I've given up on Chip -- it's not possible to hold an intelligent conversation with him, at least not on this newsgroup. I've come to dislike the person himself, not just what he says. This isn't just because of his rude responses to me, but also because of what he's done to everyone else he encounters here.

The most recent active arrivals here have been Ed and Steve. Ed tried really hard to be objective and factual -- and did an excellent job of it --, and engage in a meaningful dialog. He kept his cool in the face of the onslaught. But I sense he's pretty much given up on Chip like we all do sooner or later. (Go ahead and correct me if I'm wrong, Ed.)

Steve set an example we should all follow, but frankly I don't think I'm capable of maintaining as high a standard of conduct as Steve has shown. He deserves all our thanks and respect. He's a true professional and a true gentleman. So it's particularly hard to see him go.

So what does his going have to do with Chip? Steve hasn't said why he left, and I haven't contacted him by email -- yet. I very strongly suspect, based on several years of observation, that Chip is somehow part of the reason for his leaving. If I'm right, we can and should blame Chip for depriving us of someone very knowledgeable, objective, and willing to share information. We could have learned a lot from him. If I'm wrong, well, then, the rest of what I have to say here is still relevant.

How much longer can we put up with this destructive behavior from one spoiled bully? How can we make it stop? The obvious solution, and one I'm sure would be effective, is to simply never respond to any post Chip makes. But this has been suggested several times, and some of us just don't seem to be capable of doing it. Also, new folks keep dropping in and naively trying to engage Chip in a meaningful dialog. It's hard to watch them get discouraged and disgusted one by one, as the rest of us

have, without lending support.

We can't keep him from posting, and that's how it should be -- this is a public newsgroup. So the only way to cure the problem lies in the way we respond. Any suggestions?

In that function of the coiled coax is to impede common-mode current, it is a
balun. A suitable "W2DU" ferrite balun will function just as well, if not
better.

Source record: 179487

As you say, you can get an adequately high common mode impedance from either a "W2DU" balun or a coil of feedline. Each has its advantages and disadvantages.

The W2DU balun can be made very wideband, to easily cover all the HF bands. The coiled coax choke will give quite a high impedance over only about three bands. Of course, coiled coax chokes for different parts of the spectrum can be put in series.

The W2DU balun is pretty forgiving, as long as you use a ferrite that's suitable for the job. The coiled coax balun has to have the right number of turns and/or diameter. Some combinations are given in the ARRL Handbook.

The W2DU balun can get pretty hot if you're running very high power, again depending on the ferrite choice. The coax choke balun doesn't.

The W2DU balun doesn't really take up much more space than the coax itself. A coax choke balun has to be kept reasonably clear of large conductors or the ground.

The W2DU balun can be pretty expensive. The coax choke balun is cheap.

**Note: The comments about coiled coax choke baluns apply to ones made in the form of a relatively large, flat coil like a coil of rope. I've measured a number of these, and those measurements are the source of the ARRL Handbook recommendations. Others have wound coax into a solenoid on some sort of form. These will work, too, but I haven't measured any and don't know anything about their effective bandwidths. Like the flat coils, these would have to be wound with a particular number of turns and diameter to be effective over a particular frequency range. Some people seem to think that a solenoid like this will act like an ideal inductor, with its impedance increasing monotonically with frequency. It doesn't. Like the flat coil, it has a self resonance, and presents a high impedance only over a range of frequencies approximately centered on that resonance.

3139. Hustler mobile ant question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-25 00:00:00 UTC
From: Joe Schlatter <joe@schlatter.org>
Message-ID: <39cff1ac@news.planetc.com>
Source record: 179489

I was looking at the Hustler 40 meter mobile antenna in catalog last night and have a question.

The catalog does not show a Hustler mobile antenna assembled nor does it tell anything about what parts one needs to purchase to make a complete antenna.

As I figure it, I need:

-- bumper mount
-- spring
-- mast
-- resonator

Appears that the spring screws into the bumper mount, mast screws into the spring, and the resonator screws into the mast. Change bands by changing resonators. The resonator seems to have a telescoping end that is used to adjust for operating freq. Is this correct?

I travel a lot and am looking at purchasing a Hustler 40-m mobile and operate mobile plus run coax from motel room to car and operate from motel room.

If you engage him in a post then you get what you ask for.
If you refute what he says then you assign a value to what he says
If you debate him on a technical issue then you include him
as one of your peers
It is up to individual posters to determine if an association
with him will be of value
A person is also judged by the company he keeps
With the above in mind, why on earth do so many
participate in his posts?
Look at the specific individuals who consistently
respond to Chip, they all have a similar pattern in
their communications(the quest for the last word)
This should tell you something if you are not like minded
I too am sorry to see Steve leave but most posts now
revolve around Chip and each must determine what
value to assign to those particular discussions and that
which remains

Roy- You are so right. Chip has the manners of a pit Bull. He has caused trouble for many, by his off-NG destructive posts. At least one regular here has been hurt, financially, by his dirty tactics, and one has had his ISP service cut because of Chips multi-named postings in complaint.

I fear that Chip has done the Steve presence here the same kind of dis-service. He is capable of doing almost anything to anyone who is clearly better qualified that he. We know he lies to and about people, and mis-quotes freely. It looks like anyone with a public presense outside the NG has to cover their ass because of his uncivil behavior. I only hope he does not try to get even with Ed, in a similar fashion.

I dont know what we can do to or about him. He is clearly uncivilized and boorish, as well as vicious.

I hope this helps.

One persistent JERK has caused several people to leave the group in disgust. This behavior continues and the JERK does not appear to have a conscience or any self decency. This really upsets me as I enjoy learning from several of the experts provided that I can weed through the nonsense.

Has the group ever considered going to a moderated group with a reasonable posting policy? I know that many folks don't like the idea of a moderated group but virtually everyone dislikes the constant behavior of this one person who can't possibly have so much free time and a job. This would fix most of the problems and instantly reduce the number of posts by 1/6th without loss of any content. Remember that this one bad apple is responsible for 1/6th of the posts. I don't know who would want the unenviable job of moderator. Am I way off base here or do some folks actually enjoy this infantile behavior?

3144. Alinco two-meter handhelds for sale.

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-25 00:00:00 UTC
From: Aaron Wells <wellsa@conceptsnet.com>
Message-ID: <LbTz5.2883$kg6.309772@news.uswest.net>
Source record: 179494
Cross-posted to: alt.ham-radio.marketplace,alt.ham-radio.packet,alt.ham-radio.vhf-uhf,alt.radio.scanner,rec.radio.amateur.antenna,rec.radio.amateur.boatanchors,rec.radio.amateur.digital.misc,rec.radio.amateur.dx,rec.radio.amateur.equipment,rec.radio.amateur.homeb

I have two handheld radios for sale. Both are Alinco DJ-195 handhelds and transmit on amateur radio two-meter frequencies, which is 144 to 148 MHz. They transmit at 5 watts, and have worked on simplex at a little over five miles. Using a repeater you gain substantially more range. Both come with speaker microphones as well as surveillance microphones. They come with two wall chargers, one car charger and a suction cup antenna mount for use inside your car. Keep in mind you need an amateur radio license to transmit on two-meter frequencies. I'll sell the whole package for $300 plus shipping.

You can view the radio and specs at:

http://www.alinco.com/Products/DJ-195

Also have a Radio Shack scanner for sale. Works with trunked systems, and scans from 29 MHz to 900Mhz. Cellular frequencies are blocked. Will sell it, plus two rechargable battery packs, for $100 plus shipping.

If you're interested, please e-mail me at wellsa@conceptsnet.com or call (206) 222-7521.

Thanks.

You've pretty much summed up the situation Roy.

It is impossible to have any sort of meaningful technical discussion with the fractenna personas; it always goes to name calling and flames no matter how hard one tries to stay on the (technical) subject.

The personas are impossible to ignore either because one is new to the group and gets sucked in or the post is so outrageous one has to resond.

It is my personal opinion that the fractenna personas are, in the vulgar usage, flat out insane.

In another time, in my personal opinion, the fractenna personas would be sent to a place where they could not disrupt polite society.

Perhaps we should treat this as was done about a century or so ago. Everyone in town know who the town drunk/crazy way and basically ignored their antics as long as no one was hurt. When someone new came to town, they were told something along the lines of "Don't be concerned with old (fill in the name), he's a bit touched in the head, but he's harmless."

Perhaps this is the way to go with our current problem...

Gentlemen:
While I applaud your efforts to bring things to a logical conclusion I feel compelled to say your attempts are fraught with danger.

I seriously feel that Chip's mental state is so precarious you may push him over the edge. I envision attacks directed towards both you and Steve for being in collusion in bringing down the fractal empire. Along with gnashing of teeth and charges of "Criminal acts and deliberate malicious actions against Fractal Antenna Systems".

While I enjoy tying a tin can or two to his tail, in this case I am extremely serious. Steve, in particular faces the gravest attacks as Chip will purport that "Cushcraft antennas are out to get him". This in spite of the fact that Steve has been patient throughout the entire debacle. Please proceed with care through this minefield set by an egomaniac.

I don't want to be in the unenviable position of being able to say "I told you so..."

Warmest regards to both of you
Fred W4JLE

I'm not at all surprised at Chip's inability to distinguish between
"dislike" and "hate".

(My statement was: "I've come to dislike the person himself, not just
what he
says. This isn't just because of his rude responses to me, but also
because of what he's done to everyone else he encounters here.")

I can't think of anyone I hate. I do dislike bullies, and adults who act
in an insulting, rude, arrogant, or childish fashion, and Chip does all
of these. There are a very few people I know in this category, since I'm
generally able to simply avoid them. I refuse, though, to turn over this
newsgroup to someone who fits this description, so it looks like Chip is
someone I've got to put up with. And conversely.

3154. Re: antenna height roof vs ground

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-25 00:00:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <39D01718.C53577CF@eznec.com>
Source record: 179504

If the roof is large and solid metal, the input impedance of the antenna would act like the antenna is 8 feet from a perfect ground. At very high angles, the antenna pattern would resemble the pattern of an antenna 8 feet high. At moderate and low angles, the antenna pattern would look like the pattern of an antenna 24 feet high. If the roof isn't metal, the antenna will probably behave like it's 24 feet high, except for interaction with various conductors in and around the house, like wiring, metal rain gutters, and the like.

If you laid the antenna on the ground, it would be quite lossy and no longer resonant. Your signal strength would be down considerably (I'd guess on the order of 20 dB or so) compared to the antenna on the roof.

Why don't you make two antennas, and put one on the roof and the other on the ground. Rig up a switch so you can switch between them, and see how much the signals change when you do. Just don't assume the marks on your S meter are 6 dB apart; if you really want to know how many dB different they are, build a step attenuator and put it in line with the rooftop antenna. Switch in attenuation until they're equal.

You should be able to build the antennas in an afternoon, the step attenuator in an evening. A good weekend project, and you'll know a whole lot more when you're done.

A good idea.

You can download Star Office from www.sun.com for free and deal with those
that persist in useing Microsoft word/excell/etc.

You can download twpsk from aintel.bi.ehu.es/psk31.html and have 3 receive
windows in addition to the main window.

You can run real news readers, etc.

The only downside is there is no Linux version of EZNEC.

Jim Pennino

3156. Newsgroup jammers

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-25 00:00:00 UTC
From: Jim Pennino <jimp@mail.specsol.com>
Message-ID: <i45pq8.5sg.ln@mail.specsol.com>
Source record: 179506

While this is an open newsgroup and all are free to post, certain individual(s) have persisted in postings that have no content other than to create flames, i.e. a newsgroup jammer if you will.

Given the delays in newgroup propogation, I propose the following:

When the "jammer" makes a post, respond with something similar to the following:

This poster has, in my personal opinion, a track record of abuse and troll like posts.

Do not resond to this post. This person, in my personal opinion, is not worth the bandwidth.

For those that have doubts, go to www.dejanews.com and do an advanced search with the following parameters:

Forum: rec.radio.amateur.antenna

Author: fractenna

Keywords: "this thread is closed" 53 hits last count
"lawsuit" 47 hits last count
"death threat" 11 hits last count

Once one sees such a follow up, no further post is necessary.

Of course, all of this is purely my personal opinion based on observation of certain posters, some of which in my personal opinion are emotionally unstable.

Depends on the roof.

If the roof is metal, or there are a LOT of metal things in the roof...

Otherwise, you are 24 feet up.

I wouldn't lay anything directly on the roof even if it is wood shigles
'cause there will allways be some interaction, especially when it rains.

If it is the normal, average wood frame construction and a non metal roof,
once you are a few feet away, you can basically ignore the house structure.

In my case, there is a bunch of AC ducts (among other things) in the "attic".

Once I get a about 3 or 4 feet away from the roof, the house basically isn't
there (at 20M and above) as far as RF is concerned.

3159. RFI in in-wall speakers

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-25 00:00:00 UTC
From: jeffreys@cyburban.com
Message-ID: <39d02844$0$1346$45beb828@newscene.com>
Source record: 179509

I have some major RFI coming from my atic-mounted dipole (about 25 feet away from home theater). After some suggestions I put some Palomar RFI beads (actually the split beads) around the speaker wires (monster-brand) right after they exit the stereo.

Question: The speaker runs are quite long. Do I need to add more beads at the stereo end? If I do, will I still get it, and if so will puting them at the speaker ends (in the wall) help? The speakers are B&W large in-wall speakers (not sure of model number).

I am considering a tripod mounted beam antenna that will raise the antenna another 10 to 15 feet from the dipole. Will that help much or still too close.

Thanks. Running only 100-150 watts.

Message-ID: <t6Wz5.12489$nM4.415270@east5.usenetserver.com>
Source record: 179510

Why do you think the RFI is getting in through the speaker lines? That is the least likely place in my experience. It is extremely low impedance and extremely low sensitivity (relative to the line level wiring.) Have you performed the logical debugging processes?:

Disconnect the speaker lines at the amplifier and short the speaker lines together at the amplifier end. You now have the speaker lines formed into the optimal RFI pickup antenna. Do you still hear RFI from the speakers? No? Then the RFI isn't getting in through the speaker lines. If yes, then you are living in such a strong RF field that I would be worried about many more important things than a little RFI in my surround speakers. Have you had all the children you were planning? Have you lined all your hats with tinfoil? :-)

Reconnect the speakers and short the input to the power amp. Do you hear RFI? If yes, then maybe the RFI is getting into the amplifier via the speaker lines. You didn't say whether the ferrite beads had any effect on the RFI(!) If RFI is getting to the amp through the speaker output and the ferrite beads didn't eliminate the RFI, try adding turns through the ferrite bead. Also try small value capacitors across the speaker output terminals and/or from each side to chassis ground. The capacitors would be the "C" half of the LC low pass filter(!)

If you don't hear RFI with the power amp input shorted, then its coming in before the power amp and any treatment of the speaker lines is superfulous. You'll have to work your way back through the chain until you find "the spot".

Hi, Richard,
my old encyclopedia says that the historical Roland

was killed by Basques in the Pyrenees, poor fellow, not by Saracens
in Roncesvalles. My sympathies have always been with the Saracens.
(Visigoths have never been much thought of by historians,
nor by me, nor, I might add, by the Moors.)
At any rate, the reason I responded to Orlando, was that, fighting
bears, dragging a dead horse around with one hand while uprooting
trees with the other, and carrying on in a state of complete hysteria
and wooden wroth is what I feel like doing every time I see a
post dealing with fractal antennas that:
1. Assumes that fractal shapes are optimal in some sense
without either explaining or proving it.
2. Relies on computer-derived numerical approximation techniques
to "prove" one thing or another about something as amorphous and
vague as a shape formed by an algorithm, that, if carried on forever,
might produce something that very closely resembled the vague
mathematical abstraction called a fractal.
3. Doesn't make at least a non-mathematical attempt to
explain why the current distribution on a so-called fractal shape
is any better for producing a given far-field pattern than the
current distribution on any other object, such as a dipole, or even
a bronze mermaid.
4. Expects a simple amateur like me to accept anything as
truth without a detailed, and thorough explanation, replete with
experiments, measurements, and even, where possible, a little
diversion into -dare I type it?- mathematics.

Tom Donaly KA6RUH

(P.S. Time to do as Tom Rauch does and put my straw through the
screen and suck up some of Cecil's good whiskey - providing there's
any left, of course.)

Hi Roy:

It's also pretty silly to compare performance of an antenna at the 10ths of
a dB and 10ths of a % BW level but that's where we are.

> So here's what I'll do. I'll be glad to post any EZNEC models involved

I will be quite willing to put up any of my EZNEC files for public
distribution. I assume that Dr. Cohen will as well. I also assume that you
will post the files when they are ALL available.

Thanks Roy.

Hi Steve,

Now for the hard part. I originally wanted to include in my post that you were to pick this panel. But perhaps that was too much expectation on my part and too presumptive for those you might pick. This method would work faster though.

Why do I say faster? Because those who have railed against this comedy of errors are here only for the pleasure of the personality games - I have seen no effort to resolve issues, merely highlight and pursue them.

There is also the problem of stacking the panel with judges who are favorable to your problem (although with technical issues to be adjudicated this hardly seems a problem - but I can imagine that it could become one).

So does it simply devolve to a beauty contest where everyone votes? That hardly seems a better solution - but in all likelihood there will be some element in this no matter what direction this goes (even if it goes no where).

What am I fishing for then?

Where are the volunteers for this? There is a ton of criticism, even from the grey-backs who are a touch too much insulated from the problem, but can toss their own barbs into the mix none-the-less. No one's hands are clean in this regard. From this rough and tumble crew, no one has stepped forward with the obvious resolution and the parade of personality runs undeterred, full steam ahead.

So volunteerism does not seem to be the answer either.

To that crew so happy to pine away about the loss of congeniality, your empaneling will not be missed until we get to a manners shoot-out.

I guess its back to my first notion then. Steve, unfortunately you haven't been engaged in this forum long enough to discern the members here who genuinely could serve this capacity. Or perhaps you've been lurking long enough (which would be my hope). Either way, I will not make any suggestions. I could, there are, as I say, many to choose from. As an alternative I would offer that a choice of half a dozen names drawn randomly from those posting from the past week would easily provide an empaneled Jury that would do a far better job than the farce presented as the $1000 Challenge.

Who would be the source of the Challenge goal? Yourself. Name any criteria and submit to the Judge's modifications that occur on the basis of clarification of your Challenge. If you cannot abide, then you cease to be a participant - the Challenge goes on without you.

So to toss out the first grenade, the Challenge is:
Employing the exact criteria already established in the $1000 Challenge, members are to submit to the newsgroup their designs for the best MI2 design. Steve's will be held in escrow until the end so that no one can claim his is a copy of theirs from years ago.

If this is problematic for some poster's, then they may submit, in escrow, to the empaneled Jury who would in turn judge the technical merits without revealing the designs' details (principally the wire list). This is not the best solution, and it even goes against the grain of fair and open discussion. So, some sun-set provision must be made that all escrowed designs will be made public at some established future date.

Steve, choose your Jurists, allow them time to decline or accept, and then submit both your Challenge and your design to them. We want an honest technical competition, not a beauty contest where the obvious conclusion is the masked champion wins, remains anonymous, and the money goes to charity (such synthetic virtue is repugnant - the Camel will get through the eye of the needle before this generosity is recognized).

Hi Steve,

This is the method of the TROLL.

DO NOT RESPOND TO TROLLS.

I can appreciate you might want to respond - in part - do so. But
where there are matters that are not germane to the issues - simply do
not discuss them and do not repeat them within the response. This
will work just as well. It will also either force the correspondence
to attend to issues - to which you can respond in kind. Or it will
force the correspondence to diverge into these unrelated issues - to
which you can entirely ignore.

You are not defined by scurrilous remarks of a TROLL, so don't respond
as though you were!

I agree with Dave's overview.

There is a misplaced notion that a full-wave horizonatal loop placed
close tom earth has some gain or DX advantage over a dipole.

That isn't true.

Put up a dipole and save money. It will work just as well.

What in the hell does a person being a former anything have to do with
one's present capability in a different area?

Does the fact that you were a former undeucated child mean that you
are now an uneducated man? Your suggested "logic" is utterly bizzare.
I find it offensive that you attempt to denigrate others so often. I find
it offensive that you imply that TV repairmen (current or former) are
intellectually inferior. I find your constant attacks on Tom repugnant.
Such behaviour is abominable.

And the kicker is that Tom has demonstrated a considerable and
extensive knowledge and undertsanding of antennas on this NG,
which you cannot match. You are not even capable of recognizing
the fact.

Your mind is closed.

On a technical writing level, the words that come to mind are; overly verbose,
obfuscatory, vague, poor sentence structure, atrocious spelling.

Chip's writing reminds of a report I read once. It took close to 100 pages
to say y=m*x+b.

First of all, you are NOT an antenna engineer! You have no more expertise in the field than any other ham that has studied the field. Your credentials have nothing to do with antenna design.

Your denigration of Tom does little to elevate your position in life or on the newsgroup. Calling you an eminent antenna engineer can be likened to calling the M12 a good antenna. You have used a GA to generate a fractal shape that you can neither explain or understand why it works.

I found this from another source. I started getting spam since I made some posts. This program will mask your email address to what ever your choose when in netscape, yet retains your email identity for notmal; email operations... Hope this helps some of you.

To use a munged address for news postings with Netscape without hurting your email return address, go download FixNews
http://www.desisoft.com/fixnews/
This lovely little program lets you have a munged news address, and it supports a killfile besides. If you read newsgroups with javascript turned on, it will also prevent your browser from being hijacked by malicious posters. (Javascript on in mail and news remains a bad idea anyway)

If Netscape says it's waiting for a reply and never gets one,
the article has most likely been published.

I'm putting up an old Mosley TA-33. My question is: Can I substitue a 1:1 balun for the coax choke? Will the balun keep RF off the coax as well as the choke does?

Thanks and 73,
Scott - ka0daq

It would still not be clear that he is representing his employer in his posts. Employees do have personal opinions. For example, unless I am addressing matters related to the ARRL Lab, Product Review testing, RFI, etc., I am not representing ARRL when I post to newsgroups and reflectors. You are not representing BU, unless you are describing things related to your classroom, etc.

____________
Attention!! This is not a scam, this is the real deal--this is money in =
your pocket!
Note: I made the $6 leap of faith and it is paying off big time! You =
should too.
Just read what is below and see for yourself. This will change your =
life:

$6 Investment to make $1000s

: Make A Lot Of Money Fast !!!!!

:=20
: A while back, I was browsing newsgroups, just like you, I came across =
an article similar to this that said you could make thousands of CASH =
within weeks with only an initial investment of $6.00 plus stamps! So I =
thought, "Yeah, right, this must be a scam!" But like most of us I was =
curious and kept reading. It said that if you send $1.00 to each of the =
6 names and addresses listed in the article, you could make thousands in =
a very short period of time. You then place your own name and address at =
the bottom of the list at #6, and post the article to at least 300 =
newsgroups. (There are about 32,000 of them out there and that's quite a =
large market pool). No catch, that was it. Even though the investment =
was a measly $6, I had three questions that needed to be answered before =
I could get involved in this sort of thing.=20

: 1. IS THIS REALLY LEGAL? I called a lawyer first. The lawyer was a =
little sceptical that I would actually make any CASH but he said it WAS =
LEGAL if I wanted to try it. I told him it sounded a lot like a chain =
letter but the details of the system (SEE BELOW) actually made it a =
legitimate legal business.=20

: 2. IS OK WITH THE POST OFFICE OR IS IT MAIL FRAUD? I called them: =
1-800-725-2161 and they confirmed THIS IS ABSOLUTELY LEGAL! (See 18, h =
sections1302 NS 1341 of Postal Lottery Laws). This clarifies the program =
of collecting names and addresses for a mailing list.=20

: 3. IS IT RIGHT? Well, everyone who sends me a buck has a good chance =
of getting A LOT of CASH ... a much better chance than buying a lottery =
```

ticket!!! So, having these questions answered, I invested EXACTLY $7.92 =
... six $1.00 bills and six 32 cent postage stamps ... and boy am I glad =
I did!!! Within 7 days, I started getting CASH in the mail! I was =
shocked! I figured it would end soon and didn't give it another thought. =
But the CASH continued coming in. In my first week I made between $20 to =
$30. By the end of the second week I had a made a total of $1,000.00. In =
the third week I had over $10,000.00 and it was still growing. This is =
now my fourth week and I have made a total of just over $42,000 and it's =
still coming in...=20

: It's certainly worth $6.00 and 6 stamps !!! Also, make sure you print =
a copy of this article NOW, so you can get the information off of it as =
you need it. I promise you that if you follow the directions exactly, =
that you will start making more CASH than you thought possible by doing =
something so easy! Suggestion: Read this entire message carefully! =
(print it out or download it.) Follow the simple directions and watch =
the CASH come in! It's easy. It's legal. And, your investment is only =
$6.00 (Plus postage) IMPORTANT: This is not a rip-off; it is not =
indecent; it is not illegal; and it is virtually no risk - it really =
works!!!! If all of the following instructions are adhered to, you will =
receive extraordinary dividends.=20

: PLEASE NOTE: Please follow these directions EXACTLY, and $50,000 or =
more can be yours in 20 to 60 days. This program remains successful =
because of the honesty and integrity of the participants. Please =
continue its success by carefully adhering to the instructions. You will =
now become part of the Mail Order business. In this business your =
product is not solid and tangible, it's a service. You are in the =
business of developing Mailing Lists. Many large corporations are happy =
to pay big bucks for quality lists. However, the CASH made from the =
mailing lists is secondary to the income which is made from people like =
you and me asking to be included in that list.=20

: Here are the 4 easy steps to success:=20

: STEP 1: Get 6 separate pieces of paper and write the following on each =
piece of paper "PLEASE PUT ME ON YOUR MAILING LIST." Now get 6 US $1.00 =
bills and place ONE inside EACH of the 6 pieces of paper so the bill =
will not be seen through the envelope (to prevent thievery). Place one =
paper in each of the 6 envelopes and seal them. You should now have 6 =
sealed envelopes, each with a piece of paper stating the above phrase, =
your name and address, and a $1.00 bill. What you are doing is creating =
a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate =
service and you are paying for it! Like most of us I was a little =
skeptical and a little worried about the legal aspects of it all. So I =
checked it out with the U.S. Post Office (1-800-725-2161) and they =
confirmed that it is indeed legal! Mail the 6 envelopes to the following =
addresses:=20

:=20
:=20

: #1) Aditya Venkataraman 14215 Lake Trail Driv Sugar Land, Texas 77478=20

: #2) Charlie Baltimore 71-20 Sutton Place #3 Fresh Meadows, NY 11365=20

: #3) Shaun Littman 3061 Clubhouse Road Merrick, N.Y. 11566=20

: #4) Joseph Morris P.O. Box 37 Union Grove, Al 35175=20

: #5) M. Dixon P.O. Box 767412 Roswell, GA 30076

: #6) Lee Higginbotham 8505 Columbus Ave. #209 North Hills, CA 91343
:=20
: STEP 2: Now take the #1 name off the list that you see above, move the =
other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as =
number 6 on the list. DO NOT JUST COPY OVER THE LAST NAME, BUT REMEMBER =
TO MOVE EACH NAME UP ONE LINE!!!!!!!!=20

: STEP 3: Change anything you need to, but try to keep this article as =
close to original as possible. Now, post your amended article to at =
least 300 newsgroups. (I think there are close to 32,000 groups) All you =
need is 300, but remember, the more you post, the more CASH you make!=20

: This is perfectly legal! If you have any doubts, refer to 18 Sec. 1302 =
& 1341 of the Postal lottery laws. Keep a copy of these steps for =
yourself and, whenever you need CASH, you can use it again, and again.=20

: PLEASE REMEMBER that this program remains successful because of the =
honesty and integrity of the participants and by their carefully =
adhering to the directions. Look at it this way. If you are a person of =
integrity, the program will continue and the CASH that so many others =
have received will come your way.=20

: NOTE: You may want to retain every name and address sent to you, =
either on a computer or hard copy and keep the notes people send you. =
This VERIFIES that you are truly providing a service. (Also, it might be =
a good idea to wrap the $1 bill in dark paper to reduce the risk of mail =
theft.) So, as each post is downloaded and the directions carefully =
followed, six members will be reimbursed for their participation as a =
List Developer with one dollar each. Your name will move up the list so =
that when your name reaches the #1 position you will be receiving =
thousands of DOLLARS in CASH!!! What an opportunity for only $6.00. Send =
it now, add your own name to the bottom of the list and you're in =
business!=20

: ---DIRECTIONS ----- FOR HOW TO POST TO NEWSGROUPS=20

: Step 1) You do not need to re-type this entire letter to do your own =
posting. Simply put your cursor at the beginning of this letter and drag =
your cursor to the bottom of this letter, and select 'copy' from the =
edit menu. This will copy the entire letter into the computer's memory.=20

: Step 2) Open a blank 'notepad' file and place your cursor at the top =
of the blank page. From the 'edit' menu select 'paste'. This will paste =
a copy of the letter into notepad so that you can add your name to the =
list.=20

: Step 3) Save your new notepad file as a .txt file. If you want to do =
your postings in different settings, you'll always have this file to go =
back to.=20

: Step 4) Use Netscape or Internet explorer and try searching for =
various newsgroups (on-line forums, message boards, chat sites, =
discussions.)=20

: Step 5) Visit these message boards and post this article as a new =
message by highlighting the text of this letter and selecting paste from =
the edit menu. Fill in the Subject, this will be the header that =
everyone sees as they scroll through the list of postings in a =
particular group, click the post message button.=20

: You're done with your first one! Congratulations...THAT'S IT! All you =
have to do is jump to different newsgroups and post away, after you get =
the hang of it, it will take about 30 seconds for each newsgroup!=20

: **REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE CASH YOU WILL =
MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 300** That's it! You will begin =
receiving CASH from around the world within days! You may eventually =
want to rent a P.O.Box due to the large amount of mail you will receive. =
If you wish to stay anonymous, you can invent a name to use, as long as =
the postman will deliver it. **JUST MAKE SURE ALL THE ADDRESSES ARE =
CORRECT.**=20

: Now the WHY part:=20

: Out of 300 postings, say I receive only 7 replies (a very low =
example). So then I made $7.00 with my name at #6 on the letter. Now, =
each of the 7 persons who just sent me $1.00 make the MINIMUM 300 =
postings, each with my name at #5 and only 7 persons respond to each of =
the 7 original 7, that is another $49.00 for me, now those 49 each make =
300 MINIMUM posts with my name at #4 and only 7 replies each, I will =
bring in an additional $343.00! Now, those 343 persons turn around and =
post the MINIMUM 300 with my name at #3 and only receive 7 replies each, =
I will make an additional $2401.00! OK, now here is the fun part, each =
of those 2401 persons post a MINIMUM 300 letters with my name at #2 and =
they each only receive 7 replies, that just made me $16,807.00!!! Those =
16807 persons will all deliver this message to 300 newsgroups with my =
name at #1 and if still 7 persons per 300 Newsgroups react I will =
receive $117,649.00! With an original investment of only $6.00! And some =
stamps. AMAZING! When your name is no longer on the list, you just take =
the latest posting in the newsgroups, and send out another $6.00 to =
names on the list, putting your name at number 6 again. And start =
posting again.=20

: The thing to remember is: Thousands of people all over the world are =
joining the internet and reading these articles everyday? JUST LIKE YOU =
are now!! So, can you afford $6.00 and see if it really works?? I think =
so... People have said, "what if the plan is played out and no one sends =
you the CASH? So what! What are the chances of that happening when there =
are tons of new honest users and new honest people who are joining the =

internet and newsgroups everyday and are willing to give it a try? =
Estimates are at 20,000 to 50,000 new users, every day, with thousands =
of those joining the actual internet. Remember, play FAIRLY and HONESTLY =
and this will really work.=20

: ** By the way, if you try to deceive people by posting the messages =
with your name in the list and not sending the CASH to the rest of the =
people already on the list, you will NOT get as much. Someone I talked =
to knew someone who did that and he only made about $150.00, and that's =
after seven or eight weeks! Then he sent the 6 $1.00 bills, people added =
him to their lists, and in 4-5 weeks he had over $10k. This is the =
fairest and most honest way I have ever seen to share the wealth of the =
world without costing anything but our time!!! You also may want to buy =
mailing and e-mail lists for future CASH.=20

: Remember, HONESTY IS THE BEST POLICY. You don't need to cheat, the =
basic idea is to make the CASH!! GOOD LUCK to all and please play fairly =
and reap the huge rewards from this, which is tons of extra CASH. Keep =
an eye on the newsgroups and when the cash has stopped coming (that =
means your name is no longer on the list), you just take the latest =
posting at the newsgroups, send another $6.00 to the names stated on the =
list, make your corrections (put your name at #6) and start posting =
again.=20

: $$$!!!$$$!!!$$$!!!$$$!!!$$$!!!$$$!!!$$$!!!$$$!!!$$$!!!=20

: GOOD LUCK!!!=20

Attention!!=20
This is not a scam, this is the real deal--this is money in your=20
pocket!
Note: I made the $6 leap of faith and it is paying off =
big=20
time! You should too.
Just read what is below and see for=20
yourself. This will change your life:

$6 Investment to make =
$1000s

: Make A Lot Of Money Fast =
!!!!!

:
: A while back, I was browsing =
newsgroups,=20
just like you, I came across an article similar to this that said you =

could make=20
thousands of CASH within weeks with only an initial investment of $6.00 =
plus=20
stamps! So I thought, "Yeah, right, this must be a scam!" But like most =
of us I=20
was curious and kept reading. It said that if you send $1.00 to each of =
the 6=20
names and addresses listed in the article, you could make thousands in a =
very=20
short period of time. You then place your own name and address at the =
bottom of=20
the list at #6, and post the article to at least 300 newsgroups. (There =
are=20
about 32,000 of them out there and that's quite a large market pool). No =
catch,=20
that was it. Even though the investment was a measly $6, I had three =
questions=20
that needed to be answered before I could get involved in this sort of =
thing.=20

: 1. IS THIS REALLY LEGAL? I called a =
lawyer first.=20
The lawyer was a little sceptical that I would actually make any CASH =
but he=20
said it WAS LEGAL if I wanted to try it. I told him it sounded a lot =
like a=20
chain letter but the details of the system (SEE BELOW) actually made it =
a=20
legitimate legal business.

: 2. IS OK WITH THE POST OFFICE OR IS =
IT MAIL=20
FRAUD? I called them: 1-800-725-2161 and they confirmed THIS IS =
ABSOLUTELY=20
LEGAL! (See 18, h sections1302 NS 1341 of Postal Lottery Laws). This =
clarifies=20
the program of collecting names and addresses for a mailing list. =

: 3. IS IT RIGHT? Well, everyone who =
sends me a=20
buck has a good chance of getting A LOT of CASH ... a much better chance =
than=20
buying a lottery ticket!!! So, having these questions answered, I =
invested=20
EXACTLY $7.92 ... six $1.00 bills and six 32 cent postage stamps ... and =
boy am=20
I glad I did!!! Within 7 days, I started getting CASH in the mail! I was =

shocked! I figured it would end soon and didn't give it another thought. =
But the=20
CASH continued coming in. In my first week I made between $20 to $30. By =

the end=20
of the second week I had a made a total of $1,000.00. In the third week =
I had=20
over $10,000.00 and it was still growing. This is now my fourth week and =
I have=20
made a total of just over $42,000 and it's still coming in... =

: It's certainly worth $6.00 and 6 =
stamps !!! Also,=20
make sure you print a copy of this article NOW, so you can get the =
information=20
off of it as you need it. I promise you that if you follow the =
directions=20
exactly, that you will start making more CASH than you thought possible =
by doing=20
something so easy! Suggestion: Read this entire message carefully! =
(print it out=20
or download it.) Follow the simple directions and watch the CASH come =
in! It's=20
easy. It's legal. And, your investment is only $6.00 (Plus postage) =
IMPORTANT:=20
This is not a rip-off; it is not indecent; it is not illegal; and it is=20
virtually no risk - it really works!!!! If all of the following =
instructions are=20
adhered to, you will receive extraordinary dividends.

: PLEASE NOTE: Please follow these =
directions=20
EXACTLY, and $50,000 or more can be yours in 20 to 60 days. This program =
remains=20
successful because of the honesty and integrity of the participants. =
Please=20
continue its success by carefully adhering to the instructions. You will =
now=20
become part of the Mail Order business. In this business your product is =
not=20
solid and tangible, it's a service. You are in the business of =
developing=20
Mailing Lists. Many large corporations are happy to pay big bucks for =
quality=20
lists. However, the CASH made from the mailing lists is secondary to the =
income=20
which is made from people like you and me asking to be included in that =
list.=20

: Here are the 4 easy steps to success: =

: STEP 1: Get 6 separate pieces of =
paper and write=20
the following on each piece of paper "PLEASE PUT ME ON YOUR MAILING =
LIST." Now=20

get 6 US $1.00 bills and place ONE inside EACH of the 6 pieces of paper =
so the=20
bill will not be seen through the envelope (to prevent thievery). Place =
one=20
paper in each of the 6 envelopes and seal them. You should now have 6 =
sealed=20
envelopes, each with a piece of paper stating the above phrase, your =
name and=20
address, and a $1.00 bill. What you are doing is creating a service. =
THIS IS=20
ABSOLUTELY LEGAL! You are requesting a legitimate service and you are =
paying for=20
it! Like most of us I was a little skeptical and a little worried about =
the=20
legal aspects of it all. So I checked it out with the U.S. Post Office=20
(1-800-725-2161) and they confirmed that it is indeed legal! Mail the 6=20
envelopes to the following addresses:

:
:

: #1) Aditya Venkataraman 14215 Lake =
Trail Driv=20
Sugar Land, Texas 77478

: #2) Charlie Baltimore 71-20 Sutton =
Place #3 Fresh=20
Meadows, NY 11365

: #3) Shaun Littman 3061 Clubhouse Road =
Merrick,=20
N.Y. 11566

: #4) Joseph Morris P.O. Box 37 Union =
Grove, Al=20
35175

: #5) M. Dixon P.O. Box 767412 Roswell, =
GA=20
30076

: #6) Lee Higginbotham 8505 =
Columbus Ave.=20
#209 North Hills, CA 91343
:
: STEP 2: Now take the #1 name off =
the list=20
that you see above, move the other names up (6 becomes 5, 5 becomes 4, =
etc...)=20
and add YOUR Name as number 6 on the list. DO NOT JUST COPY OVER THE =
LAST NAME,=20
BUT REMEMBER TO MOVE EACH NAME UP ONE LINE!!!!!!!!

: STEP 3: Change anything you need to, =
but try to=20
keep this article as close to original as possible. Now, post your =
amended=20
article to at least 300 newsgroups. (I think there are close to 32,000 =
groups)=20
All you need is 300, but remember, the more you post, the more CASH you =
make!=20

: This is perfectly legal! If you have =
any doubts,=20
refer to 18 Sec. 1302 & 1341 of the Postal lottery laws. Keep a copy =
of=20
these steps for yourself and, whenever you need CASH, you can use it =
again, and=20
again.

: PLEASE REMEMBER that this program =
remains=20
successful because of the honesty and integrity of the participants and =
by their=20
carefully adhering to the directions. Look at it this way. If you are a =
person=20
of integrity, the program will continue and the CASH that so many others =
have=20
received will come your way.

: NOTE: You may want to retain every =
name and=20
address sent to you, either on a computer or hard copy and keep the =
notes people=20
send you. This VERIFIES that you are truly providing a service. (Also, =
it might=20
be a good idea to wrap the $1 bill in dark paper to reduce the risk of =
mail=20
theft.) So, as each post is downloaded and the directions carefully =
followed,=20
six members will be reimbursed for their participation as a List =
Developer with=20
one dollar each. Your name will move up the list so that when your name =
reaches=20
the #1 position you will be receiving thousands of DOLLARS in CASH!!! =
What an=20
opportunity for only $6.00. Send it now, add your own name to the bottom =
of the=20
list and you're in business!

: ---DIRECTIONS ----- FOR HOW TO POST =
TO NEWSGROUPS=20

: Step 1) You do not need to re-type =
this entire=20
letter to do your own posting. Simply put your cursor at the beginning =

of this=20
letter and drag your cursor to the bottom of this letter, and select =
'copy' from=20
the edit menu. This will copy the entire letter into the computer's =
memory.=20

: Step 2) Open a blank 'notepad' file =
and place=20
your cursor at the top of the blank page. From the 'edit' menu select =
'paste'.=20
This will paste a copy of the letter into notepad so that you can add =
your name=20
to the list.

: Step 3) Save your new notepad file as =
a .txt=20
file. If you want to do your postings in different settings, you'll =
always have=20
this file to go back to.

: Step 4) Use Netscape or Internet =
explorer and try=20
searching for various newsgroups (on-line forums, message boards, chat =
sites,=20
discussions.)

: Step 5) Visit these message boards =
and post this=20
article as a new message by highlighting the text of this letter and =
selecting=20
paste from the edit menu. Fill in the Subject, this will be the header =
that=20
everyone sees as they scroll through the list of postings in a =
particular group,=20
click the post message button.

: You're done with your first one!=20
Congratulations...THAT'S IT! All you have to do is jump to different =
newsgroups=20
and post away, after you get the hang of it, it will take about 30 =
seconds for=20
each newsgroup!

: **REMEMBER, THE MORE NEWSGROUPS YOU =
POST IN, THE=20
MORE CASH YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 300** That's =
it! You=20
will begin receiving CASH from around the world within days! You may =
eventually=20
want to rent a P.O.Box due to the large amount of mail you will receive. =
If you=20
wish to stay anonymous, you can invent a name to use, as long as the =

postman=20
will deliver it. **JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.** =

: Now the WHY part:

: Out of 300 postings, say I receive =
only 7 replies=20
(a very low example). So then I made $7.00 with my name at #6 on the =
letter.=20
Now, each of the 7 persons who just sent me $1.00 make the MINIMUM 300 =
postings,=20
each with my name at #5 and only 7 persons respond to each of the 7 =
original 7,=20
that is another $49.00 for me, now those 49 each make 300 MINIMUM posts =
with my=20
name at #4 and only 7 replies each, I will bring in an additional =
$343.00! Now,=20
those 343 persons turn around and post the MINIMUM 300 with my name at =
#3 and=20
only receive 7 replies each, I will make an additional $2401.00! OK, now =
here is=20
the fun part, each of those 2401 persons post a MINIMUM 300 letters with =
my name=20
at #2 and they each only receive 7 replies, that just made me =
$16,807.00!!!=20
Those 16807 persons will all deliver this message to 300 newsgroups with =
my name=20
at #1 and if still 7 persons per 300 Newsgroups react I will receive=20
$117,649.00! With an original investment of only $6.00! And some stamps. =

AMAZING! When your name is no longer on the list, you just take the =
latest=20
posting in the newsgroups, and send out another $6.00 to names on the =
list,=20
putting your name at number 6 again. And start posting again. =

: The thing to remember is: Thousands =
of people all=20
over the world are joining the internet and reading these articles =
everyday?=20
JUST LIKE YOU are now!! So, can you afford $6.00 and see if it really =
works?? I=20
think so... People have said, "what if the plan is played out and no one =
sends=20
you the CASH? So what! What are the chances of that happening when there =
are=20
tons of new honest users and new honest people who are joining the =
internet and=20
newsgroups everyday and are willing to give it a try? Estimates are at =
20,000 to=20
50,000 new users, every day, with thousands of those joining the actual=20

internet. Remember, play FAIRLY and HONESTLY and this will really work.=20

: ** By the way, if you try to deceive =
people by=20
posting the messages with your name in the list and not sending the CASH =
to the=20
rest of the people already on the list, you will NOT get as much. =
Someone I=20
talked to knew someone who did that and he only made about $150.00, and =
that's=20
after seven or eight weeks! Then he sent the 6 $1.00 bills, people added =
him to=20
their lists, and in 4-5 weeks he had over $10k. This is the fairest and =
most=20
honest way I have ever seen to share the wealth of the world without =
costing=20
anything but our time!!! You also may want to buy mailing and e-mail =
lists for=20
future CASH.

: Remember, HONESTY IS THE BEST POLICY. =
You don't=20
need to cheat, the basic idea is to make the CASH!! GOOD LUCK to all and =
please=20
play fairly and reap the huge rewards from this, which is tons of extra =
CASH.=20
Keep an eye on the newsgroups and when the cash has stopped coming (that =
means=20
your name is no longer on the list), you just take the latest posting at =
the=20
newsgroups, send another $6.00 to the names stated on the list, make =
your=20
corrections (put your name at #6) and start posting again.

:=20
$$$!!!$$$!!!$$$!!!$$$!!!$$$!!!$$$!!!$$$!!!$$$!!!$$$!!!

: GOOD LUCK!!!

Doug probably didn't either. Maybe he figured the antenna designer and author should come up with the design for the article. Seems reasonable to me.

This type of multiband technique is one of several discussed at:

http://www.arrl.org/tis/info/pdf/9611073.pdf

In essence, it is possible to put multiple dipoles on different frequencies
in parallel and feed them with a single piece of coax, although there can be
some interaction between the different bands that slightly affects the
tuning and SWR.

In your last sentence you seem to be implying that Steve is lying about having already made a request to join the list. A status "pending" message would seem to verify the fact that he had asked to be allowed to join. Steve seems to be a genuine, honest, and sincere person. What is the matter with you? What do you enjoy about making enemies of everyone on this newsgroup?

I'll post them under whatever conditions the sender requests. If you don't want yours posted until I get one from Chip, let me know when you submit it, and I'll honor that.

In fairness, though, I think it's appropriate for me to post on the newsgroup when I've received a file, from whom, and what the restrictions are on posting it, if any. So I'll do that.

He may not be hearing anyone because he is on six meters. At least
that's what I thought he said.

I have a stack of yagis up 150 feet, and often can listen for days
without hearing anyone. Then the band opens, it is full of twenty or
more stations, and then poof! Dead again for what amounts to a long
while at times.

Sometime soon, or sometime weeks later, I hear the same stations on
another opening.

Six meters is a great band to grow a beard on, while waiting for
signals.

I'm a former TV repairman myself. Dunno how where former radio repairmen fit on the social status, but Howard Vollum, cofounder of Tektronix, was also a former radio repairman. I'm sure it wouldn't take much looking to find a long list of well respected, even prominent scientists and engineers who once kept food on the table this way.

I wouldn't get too upset by this. Are you upset when a two year old calls you "poopy"? Same thing.

Ok. Yes it is a MFJ 9406 6-meter ssb radio. The static changes every once
in a while so I don't think the radio is dead. :-)
Just don't hear anybody talking or even CW. Someone give a shout when the
band opens up would ya? I'll keep trying but if it opens and I still don't
hear anything..... well then I guess I'll try a different antenna position
and see if that is the problem.

Just an observation:

Chip has an established history of making "less than straight forward" statements.

As far as I have seen, Steve Best is direct and to the point.

Where is the file Chip? Post your file, your word isn't good enough.

Actually, I kinda suspect the band is dead where he is, unless he knows otherwise. I have a couple of friends here in town who are in the process of getting active on 6m. They say there is little activity in general even here in the big town of Houston. I'd try it myself, but I don't have a rig for 6m. "I'm considering buying a new radio before too long, and may get a 706mk2g that has 6m" but haven't yet. As far as the match being 1.8 to 1, and limiting usuable bandwidth, thats fairly common, and I think could be cured by just shifting the center point of the antenna a tad until he gets a better match. Should be able to get it 1:1 with a little tweaking. I've done this many times on other dipoles.

I agree with the "beard" statement, but, even though I already have the
beard, I sit and listen to 50.125 when I am just keyboard pounding. When
it opens, I can get out fine, all up the band. When its dead- all I get
is computer chirps.

Try the area down in the 50.6 region- there are some beacons there.

And anyone with common sense knows that. But by now, anyone who has been around for a year or so, knows that the Frac crew has ulterior motives and can predict their behavior almost to the minute. It is standard procedure with them to attempt intimidation and embarrassment to anyone that might ask questions and require explanations which they cannot, or will not, produce. Changing the subject or direction of a thread is very common practice with them.

I also have a IC-730. It's not picky at all on the swr. I've had it
near 2:1 many times with very little cutback of power. "Maybe 10-15%
tops". You have to get over 2:1 to start really seeing a big cutback on
power. MK

Well, I am not a prominent scientist, but now that someone as respected as you, Roy, has removed the stigma from being a former TV repairman, I, too, will come out of the closet. :-)

Okay, now, former TV repairman to TV repairman, let's test how much you remember. A customer brings in a TV set for repair. You turn it on and there is a diagonal line from the upper left corner of the screen to the lower right corner of the screen. What is the defect?

Are you really saying that you are not going to write the article because the magazine editor would not design the antenna for you? Doug's expertise is not in antenna design.

Too bad; I was looking forward to reading the article.

Source record: 179566

Sideband- in another post, you asked to be informed if the band opens-
there are two mailing lists (at least) that are dedicated to 6M. People
frequently post about openings, and, of course, there is a lot of other
info there.

The lists are both called "50mhz",and both use the Majordomo system.

sent a post to :
Majordomo@qth.net
with the body saying subscribe 50mhz

send another post to:
majordomo@6mt.com
with the body saying subscribe 50mhz

Both will pick up your address from the message, send you a request for
confirmation, and then a "welcome" post.

Try it, you'll like it

Good luck- Bill

>Chip N1IR

Ed,

Reviewing articles can be headaches for the reviewer.

I've had a running problem with one author after I reviewed some of
his articles and pointed out they took several pages to say what could
be said in one or two sentences.

The one or two sentences were:

"Sometime some fractal shapes work better than other shapes in some
antennas, sometimes they don't"

"At times a fractal shape has one or more characteristics that are
useful"

In dozens of pages, the articles never explained WHY they sometimes
work and sometimes don't, or when you should use them.

One article described how a network analyzer was used to make
measurements of a rock wrapped with aluminun foil. Another claimed a
regular old tree made a great two meter antenna because the branches
are "fractal shaped", and described how the trunk could be excited by
driving a nail into the tree and worked against a ground rod.

I formed the opinion some articles were indeed Fool's Articles, that
missed the April issues. It's interesting to see someone else who I
don't know reached the same conclusion about later articles.

The author would be better off to consider the years-apart reviews
that concluded the articles were technical jokes meaningful and use
the identical conclusions the articles to improve his technical style,
rather than consider it an error or attack by the reviewers.

3218. HURRAH! ** QEX** TO RUN FRACTAL ANTENNA ARTICLE!!

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-25 00:00:00 UTC
From: fractenna@aol.com
Message-ID: <20000925081819.25741.00000784@ng-mg1.aol.com>
Source record: 179574

In a major shift in its position, the ARRL has made a policy decision to run a fractal antenna article in QEX (an ARRL publication), according to Doug Smith, editor.

In the past, the ARRL has called the submission of a fractal antenna MS "an April Fool's joke" and has not published any fractal antenna articles in its publications, since this original submission in February 1994.

The author is known to many on this NG.

I will be happy to publicly critique said article, just as I have in the past, on the ham page web site reviewing other fractal antenna articles for hams. This site gets over 4000--7000 different vsiitors, on average, a month. This is approximately the same number of subscribers as found in QEX.

There are some details to be worked out regarding intellectual property. Still, it is important to realize that the ARRL has REVERSED its policy decision--which effectively attempted to prevent this important new technology from being accessed informationally by its members.

Perhaps you may wish to let Doug know your feelings on this matter. His e-mail is:

dsmith@sedona.net

It's good to see our League opening it's eyes to new technologies!

In August 2000 I went to the egroups site and tried to join the fractal reflector. For at least two weeks, each time I visited the site my membership status was "pending" waiting for approval of the moderator. This is no lie. Perhaps Chip should check with egroups to make sure that he receives all requests to join.

Hi Phil,

Is this a 1 wavelength loop? If so, a 1 wave loop has slightly less gain than a dipole- nearly identical pattern and at least when I modeled it, the BW was a little less than a dipole. Given that, I would go with a dipole.

I'm a little confused here Chip.

Are you saying the NWS missed calling the F1 tornado that your antenna survived an F1 tornado, because they are reluctant to call 90% of tornados by name for insurance reasons??

Of course we all believe you. With your established track history of being truthful and clear why wouldn't we??

Could you please give us the reference? If this is a copyright article , held by Fractal Antenna Systems, Inc., I give you permission to quote it here.

>
>In dozens of pages, the articles never explained WHY they sometimes
>work and sometimes don't, or when you should use them.
>

Which articles?

>One article described how a network analyzer was used to make
>measurements of a rock wrapped with aluminun foil.

Ah yes!

I am very proud of that, although your statement is incorrect.

The rock was a pyrite block of fractal structure. I used to it show that Liu's article from 1985 Physical Review Letters--in which he states that the admittance of fractal shapes should be broad band-- had a confirmed experimental basis.

Broad band vibrational fractal characteristics have been explored anayltically by Michel Lapidus at UC Irvine, and several others in Europe. No one has yet succeeded in forming a general anaytical expression for the complex impedance of a fractal, for example.

Try it yourself on something EZ. Find an equation for the impedance of these three structures (as a function of frequency):

```
______________X_______________

___________X____________
I
I
_______I

_________X_____
I I
I I
_______I I__________
```

You get the idea. Move the feedpoint if you want.

Incidentally, I displayed the return loss data for the pyrite and its covered self at the 1996 IEEE APS /URSI Meeting , to great interest from the audience. They understood that the SHAPE, not the VOLUME was rsonsible for the radically different characetristics of return loss.

Could you be so kind as to suggest a different methodology as to how one can test for different return loss characteristics for a fractal volume and its complemental smooth one? I would be very interested in what your TV repair experience might bring to the table on this. I am always interested in learning new things!

Another claimed a
>regular old tree made a great two meter antenna because the branches
>are "fractal shaped", and described how the trunk could be excited by
>driving a nail into the tree and worked against a ground rod.

Could you please quote from said article and share with us?

>
>I formed the opinion some articles were indeed Fool's Articles, that
>missed the April issues. It's interesting to see someone else who I

I think it is a pity that ham radio has chosen to use reviewers--or so you claim-- that are competent technicians (such as TV repair) but not antenna engineers with defineable track records.

>The author would be better off to consider the years-apart reviews
>that concluded the articles were technical jokes meaningful and use
>the identical conclusions the articles to improve his technical style,

Actually Ed, from reading the newsgroup, it appears what Chip is complaining about is this. Someone told Chip his voice was changing pitch or he was speaking too fast when he was calling CQ's.

Chip thinks the FCC should be called to DF the bum who said that, and throw him in jail!

Hope this helps.

I am asking what the big hangup is between calling wind damage a 'confirmed tornado' or not. Is there some clause in insurance policies which does not normally cover tornado damage?

Can you fill us in? What does your policy say?

Hope this helps.

Chip- It is NOT 4000-7000 visitors- and you know it- it's that many "hits", and the faulty (?) counter on that site registers a hit everytime you select a different internal link.

I have, unintentionally, put over 20 counts on it, in one visit- another poster, here on the NG, said he added 40 on one visit. I wonder what an honest counter would show?

I hope this helps.

> swr is 1.8:1.
> . . .

It's an Icom IC-730. I haven't exhaustively tested it over every possible impedance which can cause an SWR of 1.8:1 or greater, but the SWR of the load it sees is this value or greater more often than not. And every time I've checked the net output power with the Bird wattmeter over the 18 years I've had the rig, it's 100 watts within the meter's accuracy.

My little homebrew Field Day rig also has an ALC. It only monitors forward power, so its net power output drops around 10% at 2:1 SWR.

I have no idea of the efficiency of the output stage when the rig is confronted with an SWR of this level (and made no claims about it), but there's no obvious overheating. It seems to me that a rig which can't handle an SWR of this level isn't very practical.

What does the output of your rig do when it's confronted with 1.8:1 SWR?

Mine *apparently* eats the reflected power. With a Z0-match in the system, the forward power is never less than 100 watts. With a Z0-match absent from the system, the forward power is never more than 100 watts. This appears to be true even before the protection circuitry kicks in.

Wes, N7WS wrote:
"So how many joules does it take and is the number representative of a lightning discharge?"

Sure, it represents the energy in some discharge, but the test energy was less than that in some discharges and more than that in others.

Sufficient current through a solution vaporizes it rapidly. Examples abound of the power in expanding gas.

Some readers may have seen a chunk of concrete blown from a structure by lightning. Lightning rods and air terminals are used to avoid this and other damage.

Concrete does not have to be recently wet to yet contain moisture. Moisture is always there. Concrete never completely dries. The oldest piece of concrete still has a chemical reaction going on involving its water content. That ancient piece of concrete is yet hardening and strengthening ever so slowly.

Lightning can turn the water in concrete to steam whether the concrete tops a skyscraper or is buried. It is a matter of current density through a small amount of water.

A large surface area doesn`t guarantee uniform current. Even were the concrete conductivity uniform, the conductivity of the soil surrounding the concrete is not uniform. More current flows through some spots than others. The current through a hot spot can cause an explosion.

The prudent way to avoid a split in a tower base from lightning is an external low impedance bypass from each tower leg to an external rod or other good ground connection for that individual leg. A base insulated tower should be ok if there is a good radial ground system. An arc gap somewhere will protect the concrete base.

Ufer designed his grounding system as a safety system to prevent static electricity from detonating bombs set upon a concrete slab. It wasn`t designed to dissipate lightning discharges.

Best regards, Richard Harrison, KB5WZI

Source record: 179603

I'm guessing that the software used by my web site for statistics reporting is at least typical. Here are some definitions from their "interpretations" page http://www.netstore.de/Supply/http-analyze/results.html:

Hits

A hit is any response from the server on behalf of a request sent from a browser. This includes any response from the server, not only text files or documents. If, for example, a HTML page has two images embedded, the server generates three hits if this page is requested: one hit for the HTML page itself and two hits for the two inline images.

Pageviews

Pageviews are all files which either have a text file suffix (.html, .text) or which are directory index files. This number allows to estimate the number of "real" documents transmitted by your server. If defined correctly, the analyzer rates text files (documents) as pageviews. Those pageviews do not include images, CGI scripts, Java applets or any other HTML objects except all files ending with one of the pre-defined pageview suffixes, such as .html or .text. . .

Sessions

Similar to unique sites, this is the number of unique hosts accessing the server during a given time-window. This time-window is one day by default for backward compatibility, but it can be changed with the option -u or the Session directive in the configuration file. For example, if the time-window is two hours, all accesses from a certain host in less than 2 hours after the first access from this host are lumped together into one session. All following accesses more than 2 hours apart from the first access will be counted as a new session. This way you may get an estimated number of how many sessions are started on different sites to access your server.

On my site, the ratio of "Hits" to "Pageviews" is 2.24:1, and I have very few graphics on my site. I would expect the ratio to be higher on a site with more graphics.

I figure that "Sessions" number most closely represents the number of visitors. The ratio of "Hits" to "Sessions" since I opened the site several months ago is 6.33:1. I'm sure this varies a great deal from site to site, depending on site layout and how the site is typically used.

Roy Lewallen, W7EL

Disclaimer: I'm not at all a "webmaster" -- I only know what I read in
the instructions. Any amplification or correction would be welcome.

Source record: 179605

I apologize that this is a bit long. You might find the discussion on the history of Fractal antenna research interesting though.

I am deeply disturbed with the fact that Dr. Cohen has taken this opportunity to turn this thread and technical discussion into a mud slinging match against the company I work for. My posts and statements have always been my personal opinions and do not represent the position or interests of the company. In these threads and discussions, I have never said anything negative or derogatory about Fractal Antenna Systems or the work they are doing. Dr. Cohen and I simply have a differing technical opinion as to the merits of a fractal antenna geometry compared to an arbitrary antenna geometry in the same volume, consisting of the same wire length.

The original discussion began in the thread "$1000 Fractal Antenna Challenge" where I simply asked Dr. Cohen what the stated efficiency of the MI2 loop was. After I made some very general technical comments, Dr. Cohen immediately resorted to statements like the following: "Almost everything you have said is incorrect, and the amount of time needed to educate you on the matter may be better used by your own exploration of the literature" and "Use your Ph.D. and Cushcraft experience to take the fractal challenge. Don't divert us, please, with inaccurate and incorrect conceptual speculations." In the last statement, Dr. Cohen personally invited me to come up with an antenna design that would meet or beat the MI2 loop performance. I decided to accept his personal challenge.

When I presented a design that was close, here was the response I received: "Nope. You did something wrong in your calculations. It is not efficient and the gain stinks. Been there done that. Even fractalized many". Without ever seeing the NEC file or the results, he made the following statements: "READ my info carefully. I said that your design does not work as you describe." This has been his pattern of responses from the beginning of this discussion.

Dr. Cohen then went on to criticize the fact that I work for another antenna company. Note that Dr. Cohen also publicly posted the fact that he does not sell amateur antennas and does not compete in the amateur markets. Given the fact that he does not compete in the amateur markets and does not sell amateur antennas, the fact that I work for an antenna company is irrelevant. From my perspective, this is simply a technical discussion on an amateur antenna reflector.

I would like to further respond to some of Dr. Cohen's statements below.

"Fractenna" <fractenna@aol.com> wrote in message

I did make this statement about Dr. Cohen. It was made in response to a post where Dr. Cohen again claimed that I was wrong, claimed that I misunderstood basic technical concepts and then he deliberately misquoted some of my statements. Dr. Cohen also claimed I made statements about him that I simply did not make. They were made by someone else on the NG.

I later apologized to Dr. Cohen and the NG for making this statement as I regretted stating my opinion publicly.

> <snip>

>

Actually, Cushcraft does not compete in the same commercial areas as Fractal Antenna Systems and we do not consider Fractal Antenna Systems a competitor. Based on the information I have seen on the FAS web page, their product line is more suited to handset and portable product antennas. We do not make antennas for this segment of the market.

Further, I would never discuss any of the FAS products being sold to the commercial market. I would never compare any of our products to his. Commercial pursuits do not belong on this reflector. Quite frankly, Dr. Cohen should be more concerned about his direct competitors in the commercial markets: Fractus, for example.

This discussion is about an amateur antenna on an amateur radio reflector. I do not dispute that his MI2 loop antenna works as claimed. I am simply demonstrating that there are numerous ways to achieve similar performance.

>Cushcraft does not hold patents

>

Congratulations to Dr. Cohen on his patents. He can rest assured that my company will never make a fractal antenna that infringes on any of his patents.

Not all companies or individuals value patents the same way that Dr. Cohen does. First. most small antenna companies do not try to make revenue off the IP by licensing technology. Not all new and innovative antenna designs are patented. Why tell the competition everything that you are doing. They can copy it and use it to compete against you. Anyone file a patent infringement suit? Small companies usually don't have the time nor the financial resources to file patent infringement suits.

People should also be aware of the fact that the issuing a patent is not a certification that the IP is new or innovative. It just means that the patent examiner could not find another patent that had the same claims or discussed the same technology. If a third party can demonstrate that they used similar or identical un-patented technology before the patent file date, the patent owner cannot win a patent infringement suit. He who does it first wins in court.

Irrelevant to the current discussion. I don't recall this incident. I am sure at the time we were interested in seeing what the claims were and whether or not the whole issue was just another hoax or marketing gimmick. We would not have called back because we were simply not interested.

I really have no interest in your patents but good for you in being awarded
them.

I am interested in Fractal antennas for one main reason. For the past several years I have taught an introductory course at numerous wireless conferences titled: Antennas and Propagation for Wireless Communications. In teaching this course I have been asked numerous times: "What can you tell us about fractal antennas?" I could address the issue in a limited manner but not in the depth necessary to cover the topic adequately. So I did some research on fractal antennas and the claimed performance.

There is (has been) a lot of research being done on the topic:

The first known discussion of the use of fractal geometry in antennas was made at the University of Illinois in November of 1993 by Carlos Puente. This may differ from other stated opinions on this NG.

The first use of fractal geometries for small antennas was made by Carlos Puente and Nathan Cohen. I think this may have been in 1994.

In 1994 Carlos Puente presented some ideas on using fractal antennas at a URSI meeting in Spain. He submitted a paper on the topic to the IEEE in 1994 as well. The paper was published in 1996. Carlos did his Ph.D thesis on the topic of Fractal Antennas and has published some 8 - 9 papers (that I am aware of) on the topic. He also wrote a chapter in a book titled "Fractal in Engineering". The title of his chapter was "Multiband Fractal Antennas and Arrays". The book was published in 1997.

Dr. Cohen has also published a few papers on the subject as well. I am aware of at least 4 that he has published in Comm Quart.

My interest in Fractal antennas is purely technical, nothing else. I started posting to the NG on this subject when Dr. Cohen "staked his career on the efficiency of the MI2 being higher than any other design". I asked Dr. Cohen what the efficiency of the MI2 was and it all went from there.

> The fact of the matter is that random fractals--as well as deterministic

American
> in July 1999.
>
> In other words, Best wants us to ignore the past; ignore realities; and
cater
> to his not so objectively defined interest in this subject.
>

Dr. Cohen is correct, the recent work and discussions on fractal antennas is nothing new. Techniques for lowering resonant frequency and shrinking antenna volume have been used for years. The simple fact of the matter is that fractal geometries are another way to lower resonant frequency and antenna volume. As one would expect, an arbitrary shape in the same volume with the same wire length offers similar or, in some cases, better performance.

>
> Here are the facts:
>
> 1) Best tried to 'better' the MI2 design with a helical one, using 5 inch
> diamter(!!!) tubing. A 3D design (so much for the rules)
>

This was just another option to demonstrate the fact that an arbitrary shape in the same volume with the same wire length offers similar performance. Dr. Cohen went on to ridicule this approach, inaccurately described it and then actually posted a very sarcastic thread on the concept.

> 2) Best claims to have a 'random' design that works as well, yet has not
and
> apparently will not, provide the file that he offered publicly on this NG.
>

I have provided it to other people on the NG. I asked Dr. Cohen for his MI2 file and he will not give it to me. Why should I give him mine?

> 3) Best claims to have an "(almost)2D" loop which works better than MI2.
Again;
> so much for the rules.

Dr. Cohen has a problem with the English language. Here is my statement: "I have now come up with another arbitrary (somewhat) 2D loop configuration that fits within the same physical aperture as the MI2 Fractal loop." The "(somewhat)" was in reference to the arbitrary shape.

> 4) Best claims that the 'small loop performance is SOLEY DO to the length
of
> wire used and x and y axis symmetry', a clearly incorrect assessment.
>

Just an aside: You really need to use spell check! Of course, it would have
missed "do".

If I am incorrect, why have been able to demonstrate similar or better
performance with at least 3 arbitrary shapes in the same volume with the
same wire length?

> It is time for Mr. Best to act like a scientist and stop diverting the
issue.
> If he has something then show us. As I scientist I will respond, in
praise, or
> critique, or in helpful suggestion.
>

Dr. Cohen's posts in this subject are anything but scientific. I wonder if
his peers and boss at BU would view his behavior on this NG as professional
and scientific?

> Where, Mr. Best, is the FILE? At this point I WILL NOT help him in any way
> until he backs up his claims, by providing the file to those who requested
it.
>
> Nathan Cohen, Ph.D.

I did not ask for Dr. Cohen's help.

There's the theory, and there's the practical side.
It's the influence of ground & nearby objects, plus
loss in the coax, that changes the number between
the theory (actually, I think its 72 ohms in free space)
and the measured SWR.

But it is limiting his bandwidth. 1.8 to 1 could be ignored at the
band edges, no problem. But if he's at 1.8 to 1 minimum, how
far can he tune before the rig goes into foldback?

Hi Steve,

It was all very interesting, but once again TROLLing has accomplished
its purpose to change the topic from my point which included a
CREDIBLE RESOLUTION:

Few in this venue have made note of one particular ambiguity:
>Size must fit in a form factor of about 1/8 by 1/8 wave.

must...about

What satisfies this criteria? Some form factor 17.2% larger than 1/8
waves and not others? Or will the judge mandate that his
understanding is that all designs "must" be 13.7% smaller? Either
finding is "about" right - neither of them is absolutely right
however. This may be resolved quite simply by changing the challenge
to read:
>Size must fit in a form factor of 1/8 by 1/8 wave.
Or similar, specific dimension. Or curiously, why not:
>Size must fit in a form factor of 1/8 by 1/8 wave, or smaller.

Steve has done a yeoman's job of replicating the MI2, and I believe he
has the superior MI2 design in that regard alone, much less the design
he introduces above. My comparison of his claimed results against my
EZNEC analysis of the MI2 ELNEC file show Steve's outperform it. If
Steve submitted that file - as has been clamored for - then two people
would have the best MI2 design.

Insofar the call for you to submit your work to peers, I would
embellish that so as to draw the focus to a CREDIBLE RESOLUTION:

Submit your work in escrow to a panel of judges composed of members in
this forum. This is the peerage called rec.radio.amateur.antenna.

(Let the best of commercial designers approach OUR Amateur contest fields. I am sure the members would accept any challenge, and the peerage would exercise the right of adjudication.)

To those who cannot find peers in this forum: you are probably in the wrong place, serf.

To those Wild Eyed Missionaries who proclaim their calling takes them to foreign lands (our back yard) where they have no peers - yeah. We have a College of Cardinals. Missionaries sit below the salt.

This is true, and something I hadn't considered either. A little experimentation would answer the valid question you raise. But if I were he, I'd find out why I'm not hearing anyone before spending any more time fussing with the SWR.

On numerous occasions, this technical conversation has taken some very unnecessary and very unprofessional turns. I am not sure what the real agenda is for Dr. Cohen. As evidenced by this post, it is not to engage in a simple, open technical discussion.

My agenda in this matter is very straightforward: to simply participate in a technical conversation regarding the merits of fractal and non-fractal antenna geometries.

I am embarrassed at the foolish ranting of Dr. Cohen and the fact that I find myself compelled to respond to them - most importantly when they unprofessionally address the issue of my employment. In the future, I will avoid responding to him on any matter other than a direct technical topic. I apologize for my participation in the non-technical aspects of this discussion.

Message-ID: <39CF88EE.3BF8A42A@eznec.com>
Source record: 179618

It seems rather foolish (and childish) for people to brag about the performance of their antennas based on an EZNEC model, then refuse to let anyone (or those not considered worthy) see the model. And a public challenge where challengers are required to beat an antenna but not allowed to see a model of it is pretty silly.

So here's what I'll do. I'll be glad to post any EZNEC models involved with this discussion on my web site for any interested person to download. I'll put them in a public directory, and you won't even have to look at my site itself in order to get the files by ftp.

I'll also translate to EZNEC format any submitted NEC-2 or NEC-4 file and post the resulting EZNEC file. This ability is a standard feature of EZNEC pro, which will be used for the translation. Note: Not all NEC "cards" can be translated; I'll let the person submitting the file know if it can't be accurately translated.

As I upload each file, I'll post on this newsgroup the name of the file, the date submitted, and the person submitting it. Otherwise, I won't comment on the files or modify them in any way, unless one is received with an already-used name, in which case I'll modify the name with the permission of the person submitting it. (I might also put a text file on the web site in the same directory as the files explaining what they are.)

I strongly suggest that each file be accompanied by an "antenna notes" file. This is simply an ASCII text file with the same base name as the EZNEC file, but with a .txt extension. It should include anything you want to say about the antenna or model. I suggest you also include your name and the date in this file. In the case of NEC files, put this on CM "cards" -- EZNEC pro will extract these to the "antenna notes" file. EZNEC 3.0 users can create and edit this file within EZNEC if desired. Others can create it with any text editor such as Notepad. I hate to take the role of "moderator", but since they'll be on my web site, I will take a look at these, and won't post any which contain personal comments about individuals or the like -- you know what I'm talking about. Please keep them objective and focused on the antenna and/or model. (I won't edit them in any way or reject any on the basis of any claims about the antenna. I'm simply trying to keep personal comments and insults out.) If anyone does submit a text file that's objectionable, I'll let him know, and will explain the problem. Or, if he prefers, the model can be posted on the web site without notes, and he can post any comments he likes on the newsgroup.

Because I'm not editing or passing judgement on any of these files except as noted above, I don't endorse them or any claims made for them,

either in the text file or elsewhere, in any way. I'm just offering to post them in a publicly available spot.

All you need to do to get your model posted is to attach it (and accompanying notes file) to an email message to me, with a clear request for me to post it on my web site. This offer includes only models involved with the MI2 "challenge". I won't post, or share, anything anyone sends unless it's accompanied by an explicit request to do so.

Very few of the readers of this newsgroup have access to EZNEC pro, so most are limited to a maximum of 500 segments. Please note if your model contains more than this number.

It seems that the Fractenna web site would be more appropriate for this, but I'm glad to help.

Roy Lewallen, W7EL

What rubbish!

Absolutely NOT, the technical editors of any reputable peer reviewed publication will not allow an article to be "peer reviewed" by a list of reviewers "HAND PICKED" by the authors.

Such a reputable technical editor may use some of the reviewers suggested by the authors, but will always seek out and insist on the inclusion of others not "hand picked" by the authors.

In particular he or she will seek out those who perhaps hold opposing views or who in other ways are "guaranteed" to be objective and critical. This is the only process that ensures quality results!

Clearly Chip N1IR aka Dr. Nathan Cohen seems to disagree with this process. He seems to insist that only he can select the peers who will review his work! Sort of like the Hitler theory of Scientific Research I guess.

For God's sake folks, peer review is not a "blessing" of a publication by a group of friends of the author!

Rather peer review is the essence of the "scientific method", the seeking out of criticism and tough questioning to ensure the validity and accuracy of the published results.

What?

Sara and what she has done with her high school project are simply great.

We should all support the activities of our youth in scientific and academic endeavors of all sorts.

However, even Sara would not agree that she was or is a peer fit to review the engineering or scientific output of professionals or academics. Further still, a high school science fair project is certainly not an endorsement of the validity or usefulness of any scientific or engineering work.

Aside: Sara if you are reading, CONGRATULATIONS, great work. Keep it up.

Yes, the 4 radial kit is to be used at a certain height. Going lower
increase the amount of radials.

If one can run a vertical without radials he must consider him self as
extremely lucky.
Or maybe it's not as efficient as it could be. Running 100 Watts into an
antenna that looses the most of the power into the earth is the same as
running QRP into an efficient antenna. In both cases you will get DX. But
why not having the antenna radiating the power ?

Mogens (oz1akn)

==========

Roy, you have a remarkable rig if it can provide 100 watts into any load, at high efficiency, up to the point when the swr is 1.8:1.

A PA has two (plate or collector) ratings, maximum amps and maximum volts. If the ALC is doing its job properly the PA drive will be reduced when either of these ratings is about to be exceeded.

Maximum possible power output occurs when the device is being driven at both maximum ratings.

Thus the pair of ratings also define the load resistance in ohms into which the amplifier will deliver maximum power. It is usually referred to as the "design load". Also the amplifier will be running at its maximum possible efficiency when delivering maximum power into the design load.

But as soon as the actual load deviates from the design value, either the voltage rating or the current rating will be exceeded and the ALC will reduce the PA drive. So both power output and efficiency will immediately fall.

To maintain a constant power output into a wide range of load resistances (in your case from 28 to 90 ohms) requires continuous manual reajustment of the drive level.
Throttling back PA drive simultaneously with delaying the onset of ALC does not work.

The available constant power output and efficiency with manual control would be very low and quite incompatible with the PA's true capabilities.

It should also be mentioned feedback round the ALC loop is not proportional to power delivered to the load. It is usually proportional to the reflection coefficient of the

load relative to the design load.

Reg.

I think that a peer review of one is more than sufficient in this circumstance. If you like, I can put you in touch with the publisher. Maybe you can get a bunch of you guys to complain --preferably those who work with and for other antenna companies-- and with some LUCK, maybe you can get me fired; and thrown in jail' and banished from my family; and my company kaput ;and all my 25 years of scientific output expunged from the record.

Say, Peter, why don't you tell the folks who you work for and what you represent?

Cordially,

Nathan Cohen, Ph.D.

I absolutely agree with the process as originally described. I bet my career on it everyday.

Hand picking reviewers for MS, before I submit, is an essential part of the process of how science is done.

Of course, one may try to foment trouble by confusing this with PEER REVIEW as P.O. does....

Any thoughts?
==========

Indeed it will work. But there's one big disadvantage of a variometer compared to a roller coaster - a very low Q and high loss when set to a small inductance.

This is because all the wire resistance is in circuit all the time whatever the inductance.

Might be OK for receivers. But no good for high power, multi-band transmitters.

You did indeed make that request, but as you were banned that wasn't a terribly appropriate thing to do!

You don't habd out reading assignments to a student who has been expelled..

Now: Bill Aycock was banned from the list because he took a private list post, inwhich I made an offer to send copies of the latest fractal antenna patent to list members ONLY--and re-transmitted it on this public and global medium--without any publication of the caveat.

I actually DID get some people who requested the patent who are not members of the list but readers here. This despite my effort to fix afetr Bill messed it up.

Nope; Bill was not banned because of an EZNEC file. He was banned for misrepresentation.

This process, although not really what is considered peer review, is used by most authors, relying on the draft technical review of people whose expertise and judgement the author trusts. I agree; it is almost essential to good science.

Some publishers may "peer review" by simply inquiring of the author as to whether he has had some outside review of its contents. In other cases, the publisher may send it to someone IT believes competent to review the ms and get their opinion.

I would imagine that most publishers use good judgement and common sense to review incoming manuscripts. QST, for example, can range from the publisher deciding unilaterally to accept or reject a manuscript. They also have internal editorial committee of HQ staff who review manuscripts. Those with technical content are also reviewed by Zack Lau, W1VT, in the ARRL Lab. Antenna articles are generally reviewed by Dean Straw, N6BV, the ARRL Antenna Book editor. Many artilcles are sent to one or more outside reviewers who are ARRL Technical Advisors. RF Safety articles are reviewed by the ARRL RF Safety Committee, etc.

Hi Ed--

Are you implying that Dean Straw was part of the assessment in my QST
submission (of the first fractal antenna manuscript) which the ARRL categorized
as an "April Fool's joke?"

I don't think so.

So Murray you are saying that your D2T beam will with-stand a constant 90 MPH wind better than a Shakespere vertical? Murray I find this hard to believe. Can you elaborate on this?

The D2T is a W8JK array with a terminating resistor, and broadband matching transformer. Since it is, predominently, a WIRE antenna, I wouldn't be surprised at this.

We had one of those "blows" go through here a few years ago where the wind direction shifted 180 degrees in a fraction of a second and took down 110 pine trees around the lake. However, it took none of my antennas down, damaged nothing on my property, and did no damage whatsoever to my solar boat tied up out on the lake--even though it blew trees down that flattened my neighbor's boathouse. Big refried happy deal! I think any rational New Englanders know the nature of these cells. I hope you aren't trying to "blow us away" with this epic tale.

3289. OT Comments on idea for indoor FM antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-25 00:43:09 UTC
From: Christopher Mosley <cmosley@voicenet.com>
Message-ID: <xcxz5.384$4s5.6344@news3.voicenet.com>
Source record: 179645

I was thinking of making a directional indoor FM antenna. It would be a two element yagi, using the telescoping elements from television dipoles. For the driven element the dipole would be left as is. The reflector would have the two parts of the dipole fitted soldered together by slighty expanding the thicker end of one of the dipoles.
So, both elements would be adjustable, the greatest length for the reflector being about 5' for ~89 M Hertz. The distance between the elements would also be adjustable to a maximum of about 1/2 lambda.
It would of course rotate.

I am a good mechanic and would have no problem constructing it,
On the other hand I know nothing about antenna design and would appreciate any comments on the efficacy of doing such a thing.
Also any hints or suggestions would be much appreciated, including matching to the standard 75 0hm FM receiver input.

Thanks

Well, since your opinion means shit to me Chirp and you have proven yourself to be a crome-plated asshole and not worthy of a dog pissing on your shoe. I will ignore you dripple.

Mr. Neese actually sells these antennas, so I am sure his opinion/explination will be enough.

Go to hell Chirp

Well,

Operating skill also has someting to do with it.

But, fundamentally, I agree. That's why I always point out the wbe page, which has heavy documentation of antenna performance. More than you'll find in a ham magazine article or antenna handbook.

See

That wasn't one of those. You do have these shears and other anomlaies which
just dump a vast pocket of air locally. But this one was a confirmed vortex.

Perhaps someone can fill me in though: why is there such a reluctance in
calling a tornado a tornado? Is there some LEGAL/INSURANCE distinction?

Apparently the NWS misses over 90% of F1 tornadoes.

Hi Richard,

You're correct that the proposed designs do not fit within the 1/8 by 1/8
form factor. Then again, neither does the MI2. I have not seen Chip's MI2
file or output data because he will not sent it or post it on this NG. He
said that it is available on the fractal reflector but I tried to join that
in August. After 2 - 3 weeks of "membership pending" status, I gave up on
that.

>

I would be pleased to provide the file to anyone interested (well, almost). I assume that the original MI2 file would have to be submitted as well. I think some criteria should be defined - Ie. resonant frequency, etc.

The practical reality is that the performance of each design is so close that the discussion gets silly. To argue over 10ths of dB or 10ths of % BW is bizarre. I push the discussion because I just have a bit of an issue with someone claiming that they've "seen it all" or that they are "years ahead of everyone else in the IP department". I have worked with too many brilliant engineers to listen to that foolishness over ONE type of antenna design or ONE class of antennas. There is no doubt that the MI2 performs as claimed, however, to claim that the performance is only a result of the Fractal geometry is simply incorrect.

But Chip, how can you have one in the spring -- you have pronounced this thread to be closed.

Fortunately, I am sure that all of the other rraa participants are not going to trash the thread when you reopen it the way you have tried to do to this one. After all, you would then feel just as frustrated at trying to communicate over the noise as some here have been feeling.

Do you really think your "this thread is closed" conduct is adding anything useful to the discussions here? I see it as destructive and immature.

If this problem persists, contact Brennan Price (bprice@arrl.org). Brennan has been able to do some fast calls to the FCC monitoring station from time to time. That is how the West Coast "ditter" was localized to an area; the local hams took over from there and found a ham whose transceiver had been left on when a key malfunction turned the dits on.

Steve Best said:

>I push the discussion because I just have a bit of an issue
>with someone claiming that they've "seen it all" or that they are "years
>ahead of everyone else in the IP department

I too think we need to push the discussion, especially as Mr. Best has said of me:

" In my opinion, you demonstrate a total lack of moral character."

For the record, those of us who have been in New England for a while know the owner of Cushcraft and have a fair to great amount of respect for him. He has always done well by and for hams, in particular. I have a great deal of respect for the company as a whole. However-- founders are not necessarily setting the same corporate cultures as management.

Steve Best is President of Cushcraft Antennas and a equity position holder in this private firm.

His firm, and my firm (Fractal Antenna Systems, Inc.) compete for customers in the exploding wireless markets (non-amateur). Cushcraft does not hold patents on new antenna technologies in this market and hence, as with other competitors, is at risk should a disruptive technology infringe on market share.(A publicly accessible review of their patents will show that, in a 20 year period, only 2 patents--extending the known Yagi array technology--were issued to the company. In all fairness, this does not indicate an absence of future patents but does indicate a general historical absence of innovative IP-held development).

Best is thus not an impartial observer in commenting about issues of IP, the relative 'value' of antenna designs, and so on. He has a concerted stake in assurring that Cushcraft attains a secure market share in the wireless markets, despite competitor's innovations.

The issue of Fractal's IP was, and perhaps is, of interest to Cushcraft. Two years ago, I was called (unsolicited) by Marcos Rosenbaum, who talked with me for an hour on the phone, trying to find out everything he could about Fractal's patent positions. Although I was cordial and provided SUFFICIENT SCIENTIFIC INFORMATION--as I do for any colleague in that context, I did not provide anything not publicly available. I advised him to arrange a meeting with Mr. Best: we could 'do lunch' and discuss how to take the conversation further. When I did not hear from Mr. Rosenbaum I called him several weeks later, with no return call.

At this time there were rumors floating that Fractal would not receive any patents and, just as now, the usual junk-debunkers contending it did not

provide any advantages. I am not implying that Cushcraft was responsible for such rumors; I am merely pointing out that the timing for suddenly being 'uninterested' is itself an interesting coincidence.

Now: look when Steve Best suddenly shows up to evince some interest. Go look at his posting record, and then look at the dates when Fractal announced that its first patent would issue. Again, an interesting coincidence.

The fact of the matter is that random fractals--as well as deterministic one--have already demonstrated optimum electrical performance. This is nothing new: see Landstorfer and Sacher for an early and historical taste of this. In addition, in the cases where optimum means 'frequency independent', Hohlfeld and Cohen made the clinching case for this for the relevant class of fractals, in 1999. This was written up widely in the press, including Scientific American in July 1999.

In other words, Best wants us to ignore the past; ignore realities; and cater to his not so objectively defined interest in this subject.

Here are the facts:

1) Best tried to 'better' the MI2 design with a helical one, using 5 inch diamter(!!!) tubing. A 3D design (so much for the rules)
2) Best claims to have a 'random' design that works as well, yet has not and apparently will not, provide the file that he offered publicly on this NG.
3) Best claims to have an "(almost)2D" loop which works better than MI2. Again; so much for the rules.
4) Best claims that the 'small loop performance is SOLEY DO to the length of wire used and x and y axis symmetry', a clearly incorrect assessment.

It is time for Mr. Best to act like a scientist and stop diverting the issue. If he has something then show us. As I scientist I will respond, in praise, or critique, or in helpful suggestion.

Where, Mr. Best, is the FILE? At this point I WILL NOT help him in any way until he backs up his claims, by providing the file to those who requested it.

Nathan Cohen, Ph.D.

That was an AVERAGE rate. My peak was 330Q/hr.

As best I know, only HC8A has beaten that on phone. I could be wrong though; it is physically possible to do 360 an hour (or so I am convinced).

Thank you.

Actually, I find that there are similar 'attention' tricks in contesting to lecturing. Certainly maintaining a drone--whether fast or slow--is a lousy way to hold an 'audience'.

In contesting (or contesting-like condx) most callers listen for a minute or more before they call and they--like me --are attracted by interesting and efficient operating. That makes up for a few dB difference in signals!

I have to say there are some CW operators that I am convinced are using the fingers of God--and the ears! There are some good phone ops too--K1AR is quite good. K1DG is also quite good. But the best was (is) W7RM. Listening to him work JA's was a piece of heaven. You needed a drool bucket when you monitored!

From: "George, W5YR" <w5yr@att.net>
Message-ID: <39CEBA4F.9A449855@att.net>
Source record: 179732

On this QSO rate in the contesting world:

Use a timer and measure how long it takes you to say "W5YR 59 QRZ". Now allow the same amount of time for W5YR to say "QSL 59 TX"

That is the total exchange (QSO) at most. W5YR already has the station's call and all logbook info has been exchanged..

At the conclusion of that maybe a full second, maybe even two, elapses while the contester selects another call. Then the process repeats. Most "good" contesters can run this script in about 10 seconds at most given a cooperative pileup audience.

From these numbers, I think that you can see that a solid pileup can be "run" by a skilled contest operator at at rate comensurate with, typically 10-second exchanges. That corresponds to 3600/10 = 360 exchanges per hour if the rate could be held constant.

Thus, it is not an earth-shattering accomplishment to achieve a QSO rate in excess of 300 per hour. Especially when conditions are good and the pileup is "solid" with lots of "customers" who know the game and play properly.

It still takes a good operator to *maintain* such a rate for hour after hour.

Maybe it just means that there is no application for a fractal antenna
that is worth publishing?

I don't know . . .

If it has two conductors and looks like a dipole you can center-feed it with any open wire line and a balanced tuner. It ought to radiate on any freq if the tuner has sufficient L/C range to get the swr down. Which could get pretty wild except on 20m where it should behave like any other shortened dipole. I wouldn't get a balun into the act except on 20m and only if you feed it with coax on 20m. I also doubt that anybody will get specific about any of it, this is one of those "try it and see what happens" brainstorms. It could be modeled if all the input parameters are known but by the time you waded thru that drill you could probably have it on the air.

It's a high rate but certainly not unheard of in dxing and contesting circles. In particular the dxpeditioners regularly do considerably higher rates and on ssb, too, and on a sustained basis, hour after hour, which is where the real rubber hits the road.

>

ummm . . note that he didn't say he worked 130 stations in a one hour period . . Five q's in two minutes 18 seconds is a "rate" of 130/hr. Been there done that beaucoup times. The check-ins on the 2m nets run about twice that "rate".

Hi OM,
I find this a very strange statement, did you actually send a email to VE9SRB requesting a copy for your your own personal and not for commercial use, I just wonder what the problem can be?

I received my personal copy of VE9SRB's file and verified the information for myself and and I am pleased to say that I DID NOT HAVE TO JOIN ANY CLOSED and COMPANY OFFICER CONTROLED LIST to receive this file.

I do not see any Need for the use of ANY CLOASED and COMPANY OFFICER CONTROLED LIST to disseminate information that is being freely debated on this OPEN and UNCENCORED Newsgroup.
It is my personal opinion if you use this newsgroup to publicize your VERSION of the MI2 as you have obviously done then please at least have the common courtesy to publicly and freely with NO STRINGS ATTACHED provide YOUR VERSION in a OPEN and UNCENCORED forum just like Steve VE9SRB has done.
If you are having email problems I will be more then glad, if VE9SRB has no objection to snail mail you a printed copy.

S'planation:

Cheap welcomed himself. Opened the fridge, and there were no hamburgers, sooo sorry! "We ran outta them."

He bought one more hamburger and is aging it for the spring closed "open house".

No one besides multiple frucktenna personalities was there, there will be no postings and the list is top secret. Freak was talking to himslef and applauding himself, then he ate the empty hamburger bun, drank the water from the wine bottle. Got smashed, called police that stupid hams are invading his open house which is closed. Everybody had good time.

A&P put out prize for the report from the "open chirp house" or anyone showing proof of being there. Due to huge success, the house will be closed again in the spring.

Now he is preparing to wipe everybody out in the contests. Watchout for this superhuman freaky contest machine! Just don't come close to his frequency, he will sue you. FCC is already on the red alert and prowling through your backyards with field strength meters and will be guarding his freakvency.

You gotta know how to read the freaky stuff.

I really do appreciate all the tips you all have given. I think I will put up the B&W to give it a try and because a friend was kind enough to loan it to me. I think I will look for an antenna tuner and get a spool of wire, some insulators and go to town. Anyone got an antenna tuner they want to sell reasonable to a starting out ham on a budget? Thanks again! Jon.

Roller inductors are somewhat expensive, and possibly difficult to homebrew.
I have not seen anyone build a variometer for a tuner. Seems like it would
be simpler to construct. It would need a lot of gear reduction to get a
suitable tuning rate, but that aside, it seems workable. Any thoughts?

> of a 20m Hamstick is. Does anyone know?

I don't know for sure, also the designs vary quite a bit. But I do have one 20m hamstick that is nearly resonant on 20m with no stinger at all. I'd consider that pretty much self resonant. This is bad news. But not all are designed like that. "Actually, only the worst are". So obviously, I never use it as is on 20m. I do add a 3 ft stinger to it, and use it on 40m where it works great. But the using 10m sticks instead of 20m sticks a good idea regardless of whether the sticks are self resonant. It's much better to use the stingers capacitance to tune rather than more helical windings. The stinger needed to tune the average 10m stick to 20m will be appx 2 ft long."That's what is is on my all band ant using a 10m stick as the base". If the sticks being used have no ready way to connect the stinger, you can use the small hose clamps at the auto parts store. They are perfect size for this."Use 2 to keep the stinger straight". On the helical sticks it's always better to use the longest stinger you can get away with. A stick with mostly all windings and little or no stinger whip a lousy antenna. Also, to make the best antenna using 10m sticks, you want to find the type that maximise the windings near the top, as you would a normal lumped coil. This type design much better than one where all the windings are equal spaced down the stick. Not all sticks created equal..:< MK

Greg,
It ought to work. If your not 'strapped' for space,
why not just use a 20 meter dipole? Much simpler...

[snip]

I am surprised at Chip's apparent lack of perspective on this!

I might point out that all "reputable" Universities have ALWAYS made major distinctions between peer reviewed and non-peer reviewed articles. All professional and academic authors KNOW that publications in amateur magazines are accorded little or no professional or academic recognition! What?

Authors publish in ham magazines for hams, hobbyists, experimenters and others involved in an avocation, not to build a professional publication list for their professional or academic CVs or resumes.

Professional journals, transactions, etc... are for professional or academic peer reviewed publications. i.e. IEEE Proceedings, IEEE Transactions on Antennas, IEE publications, ACM publications, Nature, SIAM, Journal of the Franklin Institute, etc...

Ham magazines and other hobby publications are for those who are pursuing an avocation not a vocation!

Everyone knows this.

This is not a discredit to ham or amateur oriented publications, rather to the contrary. Such articles may be of the highest calibre, however they are usually not subject to professional, academic, scientific, or engineering peer review. So what? That's not the intent.

But let's not go around making allusions or claiming that such publications are peer reviewed and attempting to use them to establish peer review style credibility with such publications. It just ain't so!

Ham and other hobbyist magazines often contain publications by professionals and academics, usually written by professionals or academics who are also amateurs, but for the purpose of informing and communicating with other

amateurs and hobbyists, not for establishing professional or academic credibility among professional peers.

Everyone knows this, except perhaps for poor ole Chip N1IR.

What?

Peter K1PO

3346. Re: antenna height roof vs ground

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-26 00:00:00 UTC
From: Wayne Jones <wrjones1@home.com>
Message-ID: <Xg1A5.88288$i5.3195718@news1.rdc2.on.home.com>
Source record: 179320

It's Wayne again
Thanks very much for the practical advice. I have the antenna book but it's got a lot of theory and they don't talk about this sort of thing.
I have some more 'dumb' questions. I have eavestroughing all around the house. Is there a way to make good use of this(ie vertical)? How high off the roof do I have to get a dipole or inverted v to minimize the effect of the eavestrough? I was planning on erecting the dipole along the edge of the roof directly above the eave since the roof comes to a point at the center. (cottage roof rather than gable)
tnx

Sore point with me. Last I read Her Majesty's "official" Oxford dictionary
contains something like 800,000 English language words and thier assorted
definitions. These weenie $20 consumer CD dictionaries only store around
40-50,000 words. Do you perchance know of any more comprehensive CD

dictionaries? I usually have one of the weenies on the hard drive but have not dumped one into this new computer in hope that I can find a decent one for once.

While possible, that is probably quite unlikely. I belive that if the V winding was shorted to the H winding, the circuitry could not drive both windings to full screen.

In the case I mention, the vertical winding on the deflection yoke was open and the yoke was loose on the CRT, rotated by 45 degrees. :-)

Now, back to rraa. :-)

That's the big problem with Linux at this point in it's development. I churn my daily bread via doing industrial machine design via a bunch of industry-standard high-end Windoze apps like CAD and FEA and many others of that ilk. No such things for Linux or the MAC O/S at the professional levels. Yet. I'll get into Linux on a casual basis, maybe run all my Internet activities on Linux but I can't get serious about it.

Which H.F. antenna would work better on 20-10 meters ?

A Yaesu ATS-100 mounted on the roof of a car with a mag mount or High Sierra Screwdriver antenna mounted on the rear bumber.

For 20-10 about anything will do ok. Between those two, I'm just
guessing, but I'd probably bet on the screwdriver. I'm not really
familiar with the yaesu ant. MK

Yet I tried treating him with respect on this newsgroup and was treated rudely. Ed tried treating him with respect and also received none in return. Steve's protracted attempt to be respectful, objective, and fair was met with evasion and insults.

My own experience was that Chip has been amiable and respectful -- until I questioned something he said. At that point, he decided that I had an ulterior motive, was out to get him, and was therfore deserving only of ridicule and rudeness. This is in stark contrast to an interchange of information, ideas and viewpoints among professionals or even rational amateurs, and has been his standard response to nearly any disagreement or even requests for additional supporting information.

We'd all prefer to have objective, technical discussions -- at least most of us would. I'm anxiously waiting for you gentlemen to show us by your example how to engage Chip in a mutually respectful discussion without blindly agreeing to everything he says. I for one will eagerly follow your example.

These are numbers gleaned from the literature. According to the
articles I mentioned, it is very easy to make very large errors when
attempting these measurements. Fairly large voltages (greater
than 60 volts) and currents are used on standard size specimens
(100 mm length and 50 mm diameter in a specified ASTM fixture)
to get good values for DC conductivity. This is necessary because
of polarization potentials in the material. You can't just stick your
multimeter leads on a chunk of concrete and expect the readings
to be meaningful.

Gary,
There's probably not a lot of difference between the two
antennas, in them selves. The two mounting locations would
make a difference! the mag-mount idea is very marginal for
either of these two, so you might put a 'leash' on the thing!
... or watch the rear-view mirror.

I really like the Collegiate edition. It has a much more complete selection of words than a lot of others, without being overly bulky like an Unabridged. I don't recall encountering any word used in prose or conversation I can't find there (although admittedly I read very little heavily literary prose). I do occasionally come across a word in a crossword puzzle that's not in there. That particular edition is available on CD-ROM. Looking up a word in it should be no more physically taxing than posting an email message.

>Best regards, Richard Harrison, KB5WZI

You point up something that I have a conceptual problem with.

How come this big metal thingee (the tower) can stand up there above ground and take all sorts of lightning hits without structural damage but the same steel, when encased in concrete and buried, somehow vaporizes and explodes the concrete.

Now I do not dismiss the eyewitness reports of damage to concrete due to lightning hits that have been made by posters to this forum. If they say it happened, then it happened. I just have not seen a convincing (to me anyway) explanation put forth.

So, accepting as fact that lightning induced damage to concrete tower bases has occurred, I offer two possible explanations, **simply as food for thought**.

1) I have proposed this before: the strong magnetic field produced by the huge strike current, causes physical movement of the structure. (note: 100s of thousands of TOW missiles have been assembled using Magnaforming to deform a (non-magnetic yet) aluminum section into an annular groove in a steel rocket motor housing.)

I confess that I don't have the intellectual capacity to analyze this idea; maybe something for a PhD candidate to look into.

2) It isn't heating and vaporizing of the free water (if any) in the concrete but the breakdown of the entrapped air. Similar to (exactly equivalent to?) partial breakdown in insulation systems.

Once again, just food for thought.

Regards,

Wes N7WS

Reading the original is much more satisfying than the dry facts of an encyclopedia. As for the Moors, they are taken care of by that other great work "The Poem of the Cid." If we were to jump forward in time (slightly) we would find a more appropriate tale that correlates well here: Cervantes' Don Quixote.

>At any rate, the reason I responded to Orlando, was that, fighting
>bears, dragging a dead horse around with one hand while uprooting
>trees with the other, and carrying on in a state of complete hysteria
>and wooden wroth is what I feel like doing every time I see a
>post dealing with fractal antennas that:
> 1. Assumes that fractal shapes are optimal in some sense
>without either explaining or proving it.

This is because the work has been derivative. The "scholars" have only found examples by discovery. Given the amount of work in plowing through poor fractal designs (the metaphysical equivalent to uprooting trees), one after another, mental pictures might emerge where the researcher finds correlation, but this is tenuous at best, and given the paucity of discussion these suspect correlations appear to be strained too.

> 2. Relies on computer-derived numerical approximation techniques
>to "prove" one thing or another about something as amorphous and
>vague as a shape formed by an algorithm, that, if carried on forever,
>might produce something that very closely resembled the vague
>mathematical abstraction called a fractal.

Nothing has been proven, there is no basic or fundamental property enunciated that can provide for a position to defend. There are many observations made, certainly; however none of these constitute a science of the subject. You might expect a denouncement of this last statement, but I seriously doubt you will ever hear a compelling counter example.

So, to steal the march on that counter example, my work has shown correlation between the degree of complexity of design to the resonance of the design. There is nothing tied to any particular algorithm though, it is far simpler than that.

The employment of computers is simply the discovery process automated (which thus demystifies the bear strangling). What you are reacting against is the sanctimony that comes with some announcements. Strip out this excess baggage and you will find very little - but what you do find may be meaningful. Unfortunately this moment of Aha! is trounced by the messenger.

> 3. Doesn't make at least a non-mathematical attempt to
>explain why the current distribution on a so-called fractal shape
>is any better for producing a given far-field pattern than the
>current distribution on any other object, such as a dipole, or even
>a bronze mermaid.

This, again, is because such "winners" are found, not forecast. A non-mathematical attempt to explain would have to go back to the mental picture drawn during the process of sifting through the innumerable poor fractal designs. Again, fractals do not trump common sense nor experience.

I covered this many times with my critique of the k2. The common explanation for its properties is wholly unrelated to the beingness of fractal and I demonstrate that quite clearly with my competitive, simple design of the Flying H. All the mechanisms of gain for the fractal are the same for the Flying H. As Steve has pointed out, differences that amount to tenths of a dB have little merit in anointing the claims of fractals.

> 4. Expects a simple amateur like me to accept anything as
>truth without a detailed, and thorough explanation, replete with
>experiments, measurements, and even, where possible, a little
>diversion into -dare I type it?- mathematics.

I would be surprised if anyone accepts fractals on the basis of a detailed and thorough explanation (and so on). This would put anyone to sleep, I have at least 300 pages of such data that draws nary a word of discussion, so detail and thoroughness is obviously not the magic bullet. There was talk about the necessity of real, constructible designs. I provided several to which there was no response (here - the Army is interested tho'), so even this is obviously not the magic bullet either.

It is more than obvious that interest in fractals is not technological so much as comical. It is the parade of personality that keeps it on the midway. Without that, it would be another carny freak side-show. But this does disservice to freak-shows. One example from moviedom is Todd Brown's "Freaks" which at least had a moral (and one that works perfectly here with a dove-tail fit).

>
>Tom Donaly KA6RUH

Hi Tom,

We might spend more agreeable time in the examination of the lives of 17th century gentlemen and their writings in their diaries (Pepys is my favorite - he also was Newton's editor for Principia). I am tempted to quote one of the "experiments" conducted by the Royal Society back then, it makes just as much sense as fractals, and was taken as seriously (and with as much doubt). It correlates to your expressed desire for Cecil's good whiskey, and also presents a solution for those who suffer from poor behavior.

Hi Roy,

Having them hoist their own petard will not make that bomb any less explosive. It is not a solution and is tacitly acknowledged when distancing is so obvious a factor in their congenial relations. However, such distancing is part and parcel to not responding to trolls. This is, in itself, a solution.

However, where is the support for the dis-enfranchised? It is one thing to pine away about the human condition and focusing on the possibility of finding redemption for the terrible sinner when there is the technical side of the correspondence that goes wholly neglected. This is simply the parade of personality supported by apathy and evidences a total lack of interest in the subject, but rapt attention in the comic.

No one's hands are clean in this matter.

Here is the abstract for patent 6,104,439:

United States Patent 6,104,439
Jeong , et al. August 15, 2000

Method and apparatus for motion estimation

Abstract
A method for motion estimation includes steps for constructing a first image segment representing a portion of present image frame and a second image segment having a plurality of image segments of an adjacent frame, comparing said plurality of image segments of said second image segment with the image signal within the first image segment, and generating a number of error values, detecting a first motion vector at one scale of resolution using the generated error values, outputting the error value associated with a reference segment pointed by the first motion vector, and the error values corresponding to the reference segment shifted by one unit of selected resolution respectively in selected direction(s), generating a second motion vector in finer scale of resolution using the output error values, and summing the first and second motion vectors.

I was using the term interchangeably with "feed-point" impedance, a useage that appears to be somewhat common. In reading the responses to my statement, however, I believe that useage to be incomplete and misleading.

That's good advice Ed.

Evasiveness is not an insult. It is simply means someone doesn't want
to talk about something.

Does anyone have a KLM 435-18C or similar Circular Polarized
UHF satellite antenna hanging around the shack still waiting to be
put up or sold ?
Perhaps you've put it up and aren't using it any more
I'm interested in buying it and playing with it for a while.
tnx 73 Bobby K4BGA

3391. Poor QEX editing?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-26 00:00:00 UTC
From: atkes@imap1.asu.edu
Message-ID: <8qr8h3kq1@news.asu.edu>
Source record: 179365

I just received the latest QEX/Communications Quarterly magazine from the ARRL.

I was surprised to see, in the letters, a critique by Walter Maxwell of a Communications Quarterly article by Steven Best (which was apparently an article critiquing an earlier article in QEX by Walter Maxwell), followed by a letter by Steven Best and a follow up letter by Walter Maxwell. Apparently there have now been 2 articles and 3 letters published, on how to analyze simple transmission lines and networks, that do not agree with each other. I confess that I have not read either article; I figured I understood network theory already.

In areas where things are unknown, measurements in dispute, problems unsolved, or where people have differences of opinion on what is the best way to do something, there can be controversies. Unless I misunderstand, (always a definite possibility) this is a disagreement about simple network analysis (apparently, among other things, they don't agree on various input and output impedances of a T-network with terminations given). Since it is a well understood area, it seems strange that the editor and/or technical advisors are unable to figure out what is correct. Perhaps someone on the newsgroup understands the politics of this and can explain to me what is really going on.

Jim, a nicely put posting.

I am sure most people would agree with you, that there are certain jammers on this newsgroup. It still amazes me that the same 4 or 5 people continue to ruin what is a really good NG.

I don't know about you, but if I meet someone on the street who is obviously unstable, I walk away quickly. I wonder why it is that a few here seem to want to continually "wind him up".

The whole NG would benefit from the saner ones keeping their thoughts to themselves.

I am sure that many, many contributors to the group have gone away purely because of the childish like mentality often seen in NG posts.

Many people may like to try the filters which are available on most e-mail packages. I
for one have filters on certain guys and subject matters. It does make for some interesting
NG threads where you don't see the "silly" replies !!

Regards, Malcolm...

Walt Maxwell had several people peer review his reply to QEX.

Walt is really good about soliciting and considering outside input and comments, changing his opinion with convincing evidence, and admitting mistakes.

I think very very highly of Walt Maxwell. Please let me know if you find any flaws in his statements. I'm sure Walt would also value your input.

mono-ton-ic, adj. [first known English use 1797] . . . having the property either of never increasing or never decreasing as the values of the independent variable or the subscripts of the terms increase.

-- Merriam Webster's Collegiate Dictionary.

Hence, an impedance that increases monotonically with frequency is one whose impedance keeps going up and never goes down. This isn't a particularly unusual word -- you'll find it used often in technical and mathematical articles and texts.

I highly recommend getting a dictionary. They're very useful in the process of communicating. If you don't like books, you can get it on a CD-ROM for a modest price.

3396. Re: RFI in in-wall speakers

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-26 00:00:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <39D04F8A.908E048F@eznec.com>
Source record: 179430

You don't get an awful lot of impedance from a single bead. It's best to wind several turns on a single core, since the impedance goes up as the square of the number of turns. 10 turns on one bead equals 100 beads clamped on the wires. This might not be practical, though, if your speaker wires are large diameter and you don't have a big core. To be most effective, the cores should be long and thick.

Be sure to use the same treatment on the power cord, too, and any other long wires entering the stereo that can act like an antenna for it. Always run both conductors through the core(s) together -- don't try to split them and run them separately.

If your feedline also goes close to the stereo or other wiring, a balun or some other method of balancing the feeline conductor currents might help also.

Roy Lewallen, W7EL

Gee, that would requre reposting every post you've ever made to this newsgroup, Chip....

Why don't you just make the NEC file for the MI2 or the FQY or ANY of your antennas publicly available on this NG, and quit playing these control-freak games.

The reason some on this newsgroup haven't attempted to join is because we've heard what happened when others have tried. Steve Best says his membership is still "Pending", and you know what? Unlike you, I BELIEVE HIM.

Steve has been nothing but straightforward on this NG, and in the emails he and I have exchanged. He is a highly respectable human being, with alot of personal knowledge he is actually WILLING to share.

Your insistance that people join your reflector sounds to me like a way for you to collect email addresses you can sell to companies to spew spam to their mailboxes, and a way to sate your thirst for control.

I won't be joining your reflector... I already get enough spam.

To the others on this NG, I apologise for this rant. But I felt it needed to be said.

Arright! Everybody outta the pool!

That's twice for stutters on 2 different machines with 'doze95 and 'doze98, and OE4++ and OE5++, respectively.

Is my ISP (copper.net) possibly complicitous here? I just now asked for their help.

Could one of Micro$quish's stealth updates have caused this? I get 'em almost daily.

Is it the approach of the new moon?

> This one took off a few shingles from a couple of the houses.

I've watched straight line cold front winds crumple a past push up mast I had like it was a soda straw. A guy broke first, and there wasn't time to do anything except watch it go. I estimate the winds at 80 mph +-. I've had hurricane winds "alicia" that converted a 10m GP I had into an arrowhead." All the radials and radiator pointing the same way". Many, many downed trees in that storm and the winds a fairly wimpy 105-115 mph. I used to live in Kansas back in the 60's. " Wichita, and the KC area" I can tell you stories about real tornadoes. They are like a weekly thing up there it seemed like. Most houses up there have basements to huddle in, and we used ours quite a bit. I've seen whole blocks of houses flattened like a gas explosion. I've even been camping when a tornado hit our camp. We had a coleman camp stove on a stand in front of the tent. We huddled in a big army tent when it hit. The walls of the tent started flapping in and out like it was thinking of flying off. The tent stayed, but we watched the camp stove fly away in the wind. We never saw it again. Here in Texas, 85% of the tornadoes are fairly wimpy in comparison to Kansas. But there are exceptions, like the one recently that obliterated the place. The panhandle gets a few bad ones from time to time. Here in Houston, it's hurricane country, with the occasianal wimp tornado. But we're way overdue on a bad hurricane. A bad one, say 150 mph, will obliterate this town. It will be really bad news. The skyscrapers start raining glass down on the streets from being broken from flying gravel off the roofs, the trees start falling left and right. Many people get flattened from trees falling on their houses. This all happened during alicia with it's wimpy winds. A 150 plus storm will be total distruction for this town. Houston wasn't built for hurricanes. All the big buildings are glass. Even with all this, I still think hurricanes are fun to watch though...g The last one had power transformers blowing up in every direction. They made the sky glow green. MK

Yes Dave!

The 6LW6 had an anode that folded as much metal as possible into a
small area, giving the ability to transfer lots of heat.

It amazes me we have the same technology in antennas.

I see you have your new fractal server working, posting posts within
posts. Nice work, but even that won't help you break the posting
record set by the NG troll and he is doing it multi-single!

Sorry folks. False alarm. I checked NWS records and they reported NO
tornados in Chip's area the day in question, not even F1's

Damage reports that day to the weather service from that area was $0

Looks like it was an imaginary F1 tornado that the fractal survived.

Hi Tom,

Please present published data which reveals that a fractal antenna has been used--and indeed is a so-called property-- to generate and diddipate heat.

So far, you have not been able to present any support for the numerous assertions you have made, at this count almost a dozen in the last day.

Am I incorrect in understanding your MAGNTITUDE of dislike?. You didn't say 'I dislike this' for example. You asserted that you strongly dislike ME. Personally.

Would you wish me to beg your forgiveness for some bogus violation?

IMHO, your public post is an efort to make me look like something I am not. and makes you look, well, let each make their own assessment.

But please: I am not unhappy to severe all contact with you personally, based on your embarrassing and vile response. That would seem for the best

Hi Steve--

Can you tell us what an aperture engine is, and who came up with it?
I'm sure you feel it is important to explian given that it is
important to put in all your posts.

Sounds about right to me; except this one did cause damage sporadically on a 3 mile path. Did about $5K damage to the house and yard.

The 'funniest' thing is it took my garbage barrel and dumped it on top of the roof of a neighbor 200 feet away(and rolled off). Found the lid about 1/4 mile away.

Too bad I didn't have some geraniums up! Would have had a pink tornado!

Hi Roy,

After some three years, last November or so, I too took the pledge.

There are no two ways about it:
DO NOT RESPOND TO TROLLS.

You cannot reform the unrepentant - especially those that revel in
their role. What bothers me more is that for every 10 (100, 1000)
postings that amount to nothing other than posturing, respondents seem
more satisfied with engaging in the braggadocio rather than posting a
single entry to support the legitimate correspondence trying to unfold
around them.

I am sorry to see Steve depart, his presence allowed the discussion of
fractals to go further than three rounds before the circus began.

It very often ain't that simple or easy. We don't know the guy's installation circumstances. He might very well be one of the innumerable apartment complex dwellers who only have a balcony railing available to clamp a short mast, dipole & feedline. There have been prior discussions in this NG on that topic. Personally, I don't have any time for any of the "small-wire-wound-around-small diameter-fiberglas "solutions". Assuming the guy is a balcony dweller it strikes me that maybe his best bet might be to put together two eight foot Bug Catchers rigged butt-tobutt which are not resonant on any ham band and once again go the open line and tuner route. If space is a real problem then cobble together a pair of four foot Bug Catchers.

The length of a coax feedline doesn't much matter on HF. The only name of your game is to get as much wire (length) as you can install as high as you can possibly get it. Don't get swallowed up by the worship of R50 + j0 ohm coax feeds, you have other options.

>this antenna about 8 feet in the air as I live in a 'no antenna' apt.
>complex and currently have it hidden under the wooden balcony
>of the apartment above me. The SWR is currently about 1.8 at 50 MHz.

This is almost exactly what EZNEC predicts for a 6 M dipole 8 feet above ground. The antenna, when resonant, would have a feed-point impedance of 90 ohms, an SWR of 1.8:1 to a 50 ohm feed line. The antenna is working perfectly.

If your transmitter is delivering full power into 1.8:1, there is nothing that needs to be corrected. If I assume that you are using 25 feet of RG-58, the losses are as follows:

RG-58 has a loss of 3.6 dB/100 feet. Your 25-foot section has a loss of 0.9 dB. The *additional* loss caused by operating the 25-foot line at 1.8:1 SWR is 0.1 dB, for a total loss of 1.0 dB. To put it in perspective, an S unit is usually 6 dB. If you are using 25 feet of RG-8 foam, the total loss at 1.8:1 SWR is 0.3 dB.

> If I tune the frequency either up or down on the analyzer the
> SWR goes up. Does this mean that the antenna is tuned
>as good as is 'possible'...?

Yes, it generally does. Most antennas impedance varies with height above ground. In free space, a dipole would have a 72 ohm impedance. Most dipoles on HF are fed with 50 ohm line because the impedance *at typical heights above ground* is often close to 50 ohms. But it can vary from less than 20 ohms at very low heights to about 90 ohms at about a half wavelength.

The octal base 6LW6 used in late Admiral Color TV's was a brute. It
had more CCS dissipation than an 811A, but unfortunately was only
used in those sets! It had twice the dissipation of most sweep tubes.

The great performance advantage was due to the fractal shaped anode.
The large surface area allowed it to dissipate huge amounts of power,
just like fractal antennas.

Hope this helps.

I see no reason to go by his offer. Roy has now publicly gone on record as saying that he hates me. That is a personal and deeply troubling statement from someone who, at least from a programming niche, otherwise commanded respect from me previously. But disruptive technologies commonly endure such sordid and personal trials. Frankly, I am in no way fazed.

The objective of the fractal antenna reflector is to provide info to those with a bona fide interest in the topic. The fact that some ask for info or demand info without going through this simple process of joining, indicates that they are simply not serious in their requests and their actions.

Again: the MI2 file is made available, on request, to members of the fractal antenna reflector.

Copies of patent 6,104,439 are available on request to members of the fractal antenna reflector.

Also, I have just announced the re-availability of the Hohlfeld-Cohen FRACTALS paper on frequency independence, to members of the fractal antenna reflector. (This is the work described in July 1999 Scientific American).

There will be additional free offers, as always, with time.

ONLY on the fractal antenna reflector.

Well, yeah. Only I would suggest no spring at the ball mount, and a resonator spring instead. It goes between the mast and the resonator.

Another thing: the Quick Disconnect is darn handy.

And, the fold-over masts fatigue and breag at the hinge. I like the one-piece mast better.

That's a major accomplishment! Getting Roy Lewallen to hate you must be like working country 390 QRP. I know it took a lot of work and a lot of persistence to win that honor, cause I don't know anyone else who's ever achieved it!.

Face it, Chip. Virtually everybody on here probably hates you. Perhaps you never repaired TVs, but lacking more utilitarian skills, I'm sure you're at least a former bed-wetter.

Yep, do what I did a long time ago, add every form of Chip, Frac, etc. that you can think of to your spam filter. Then you will never even see his posts. And if you add it as a subject line filter also, you will never see any of the responses to any of his posts...

Source record: 179384

Hello Cal,

I recently bought an HS-1500 o use in my first effort at mobile operating since using a Gonset Communicator II in my father's car in 1960. Before installing it on our motorhome, I put it on a tripod in my very wooded front yard in Connecticut to try it with my new ICOM 706IIG. (This, by the way, is my first solid state gear in 40 years as a ham!)

My principle objectives were to:

1. Become familiar with the antenna in general,
2. Get a "feel" for it's tuning characteristics, and
3. See if it "gets out" at all.

I mounted the antenna on High Sierra's tripod using the wire lathe counterpoise arms supplied. Using the ICOM 706, I made one contact on 75m to North Carolina where I was reported as "very strong". I made the second contact on 17m to Northeastern Belgium and the third contact on 12m to Northeastern Scotland. I quit there. Certainly not conclusive testing by any means but enough to tell me that it clearly is going to work out fine.

The tuning mechanism worked as well as expected although some type of indexing to enable returning to a previous position would be very welcome. Lacking that, even travel limit switches would be vast improvement over the rather funky and ambiguous LED end-of-travel indicator.

Everything considered, even though I have yet to use it mounted on a vehicle, I'm optimistic that it's going to work out great. Hope that helps.

Regards,

Denis W1AOK

OK, so they hate me--according to you.

That changes nothing for me.

I have a family and friends and meaningful work to a focused and dedicated life. I enjoy helping others and do so on a daily basis. I enjoy discovering the workings of nature and do so at every opportunity.

I enjoy the excitement and satsifaction of bringing into being a new technology and field of science, and extending the reach of others.

It is a full and meaningful life.

And of course, there is Mozart with Nachtmusik kissing the evening air as I type.

I love being alive and will continue sucking its marrow.

Just wanted to reassure you of my course and resolve.

With Best Wishes,
Chip N1IR

MFJ 247 HF SWR Analyzer

Looks like the newer MFJ 259. Digital display.
Works 100%, looks like new.
Comes in original box, and with original manual.

$75 plus shipping.
You can see an image of it here:

http//members.home.net/sgiron/mfj247.jpg

Source record: 179395

Bill, the counter can count either discrete IP addresses visiting a page, page visits, or more commonly "hits." A hit is typically any request for content. A text only page would only have the content associated with the text on the page accounting for one hit. However, if the page also included images, the number of hits can be quite high. Images can be visible or invisible (space holders).

For example many web page designers will use small images as space holders to control the positioning of visible elements on a page. I have seen as many as 200 small space holder images on a single complex page. Each image can account for a hit, meaning that a single visit to such a page could generate as many as 200 hits.

Unless you know what a counter is counting, and how the pages being counted are constructed, the counter's information can be considered as no better than an ordinal scale because while the counter allows the webpages or websites to be rank ordered, they in fact don't take into account equality of differences between pages or websites.

Source record: 179397

Hi, it's Wayne who started this post.

Does the roof constitute a ground? For instance, if the roof is 16 feet high and the antenna is 8 feet over the roof, is the antenna now 24 feet above ground or is it now 8 feet?
Is the antenna is better on the roof because of it's sheer altitude or height above ground? What if I just laid it on the roof?

Wayne

With respect to one individual who I (first I believe) refer to as "Chirp"-- the moniker seems apt considering the way he shifts around when his button is pressed -- I offer the following:

From time to time I have tried to engage this individual in serious technical discussions in the areas of network analysis and antenna range measurements. While I do not claim to be an expert in these areas, I do have some profession skills and experience in both of them. Alas, I have often failed to maintain a level of professionalism and have fallen into pointless bickering, which in hindsight, I regret.

On other occasions, I entered into banter that I felt was more-or-less in jest but once again in hindsight I realize was non-productive and a waste of bandwidth.

In private communications with others, I have expressed the opinion that "Chirp" was simply jerking people around in jest and surely could not be serious. My correspondents felt that I was mistaken. Upon reflection, I tend to agree with their assessments.

Unfortunately, my newsreader does not support kill files, so if I continue to peruse this group, I pledge the following:

I will not engage in any further discussion of topics with subjects that contain the words, "Fractal", "Lawsuit", "Challenge", "Record", and "Web Site Hits" -- for completeness and the hell of it -- I'll include "Carolina Windom" and "GAP Titan" too.

Neither will I respond to any posts or threads that are authored by or contain quotes by "Fractenna", "Chip", "N1IR", "NC", "Phil", "Nathan Cohen, PhD", "Cohen dog", et al.

The best way to deal with malicious jamming and interference on the ham bands is to fail to acknowledge the perpetrator's presence. Should work here too.

Wes Stewart, N7WS

Very well put Roy, time to end this nonsense.
I am guilty of getting provoked, getting infected with his "style" and trying to straighten few things, sometimes with parody, but nothing works. I think the only way is to ignore NCs and if the casual innocent new antenna groupie stumbles on NC and engages him, we should have a private email going to him with warning what awaits and with request to read the F... archives before deciding to engage.
(Maybe we should close every thread Fractennas write?)

I solemnly pledge not respond to F... trolls from now on! So help me dBF!
Any compadres?

Yuri, K3BU, VE3BMV, VE1BY, P40A etc.

6KD6? They were used in FTDX400 and 560, pair of them of them ran 500W.

I too have to confess of doing TV and radio repairs, to make it worse - behind the Iron Curtain. Knowing where to kick the radio was the most difficult skill. I also have to confess that I am mechanical engineer and not electronics, and before that I was machinist working on lathe, milling machines, welding and other dirty work like in brick factory and on the kolchoz picking potatoes. How's that for being unqualified with all that dark past. On hell of a life school, 80% what they teach at university, I never used. It might have exercised my brain, but I wish I used some more useful stuff to do that. 80% of knowledge that used in my life/profession was self learned.
Comparing what repairmen write vs. some ass. professor, makes you wonder, eh? Maybe Chippy should have taken TV repair classes instead of who knows what?

Spring at the base is handy if you use guy string to the front of the window.
By pulling on the string, you can bend the antenna forward when needed to clear
the obstacles. I always use the guy string. Keep the top of my antenna at
around 13 ft from the ground.
Quick disconnect is handy if you need to hide the antenna frequently, or when
entering low parking garages.
To get better efficiency I used 80m resonator form and wound new coil for 40m
using #14 copper wire on abt 2" diamter PVC and clamped to metal ends with hose
clamps (I run amp also abt 500W)
Works very well. I had no problem with fold over masts.

Hi OM,
Thanks for asking I feel quite well come to think of it, I share your concerns but as you know, the rules on disclosure are quite clear, absolutely clear.

I am truly overjoyed to see by your answer that you have finally received your own PERSONAL and NOT for COMMERCIAL USE copy of the VE9SRB EZNEC MI2 Design, I am truly happy for you that you did not have to wait for the snail mail as I understand that it tends to get a bit slow this time of the year in the New England area.
I am truly Glad that you have made the correct decisions to not only publish your version of the MI2 in that CLOSED and Company OFFICER CONTROLED LIST, I am sure that all of the readers of this news group await your OPEN PUBLICATIN in this world wide and OPEN newsgroup with true enthusiasm as winter approaches.

Hope that this helps.

And may God Bless.

I use their standard masts, mounted on the fender (72 Buick LeSabre), but I replaced the Hustler whip tips with CB tips sold at radio shack. I adjust the turns on coils to resonate the antenna. At the base I use about 5 turns of 1/4" copper tubing to ground to match to 50 ohm coax.

I received a quote for a bunch of 2" (man is that expensive) as well as 1 3/4 seamless heavy wall from an outfit in Flint Michigan.

I'm not sure what I did with it as I went with steel (for masts), but it may still be around here. If you still need a source, I'll try to find it.

F-1s are not much to worry about except for mobile homes and old houses not
ancored down.

On weather watch, two, or three years ago, several of us ended up in one
that was basically clear air.
Inside it was calm, around the edge it was pretty breezy. My yard is 200
feet across and it was only slightly farther across than that...maybe by 50
feet, making it 250 feet at most.

My neighbors wife went running for her house and hit the edge head on. For
a few seconds she was just stopped, leaning into the wind, but going
nowhere.

It made a lot of noise taking the tops out of the trees (just the small
stuff) and that was about it.

Even a low F2 is not terrible except for the stuff flying around....Strong
F-2 and higher is not something to play around in.

This one was just skimming the tops of the trees and went right over the
house. No damage to the roof (seal down shingles), but the neighbors lost
some shingles.
Guy to the East lost a whole tree and it took the top out of a big Oak tree
about 600 yards East.

We get straight line winds that are much worse and do far more damage.
This one took off a few shingles from a couple of the houses.

Jeff,
You might also try a 0.001mf@50v(?) across the speakers. Make
multiple
turns on the 'beads'. Moving the antenna further away always helps.
You
didn't say what frequency. If it's HF don't worry about the RF
exposure,
unless you sit on the antenna (literally!). VHF and UHF, the exposure
is
a different story...

Joe,
Should have mentioned this but forgot it. Most problems
with mobile antenna deal with a good ground to the vehicle,
especially on the newer ones. A ground strap from the
mount to the frame is a good idea. Using braid from coax
is not a good idea, it deteriorates in weather, ground varies,
the antenna acts 'weird'. Better to use copper strap or
something simular.

There is another viewpoint that, in my opinion, goes a little beyond the surface.

In feedback control systems there is a thing called "damping factor". If a "pole" in the system is too close to the frequency axis, a small perturbation causes large oscillations that die out slowly, or can even result in "limit-cycling".

The fix for this is to add things to the feedback loop that stabilize the system (move the poles into a more stable region). Or to be careful how we energize the loop.

It is obvious to me that there is an analogous phenomenon here, a personality, a temperament, that is easily perturbed, tends toward overreaction and is not under adequate control. Invariably, the underlying factor is a psychological problem of some kind that I am not competent to evaluate and do not want to try to get into.

My personal opinion is that this individual, despite some behavior that many would call outrageous, deserves some compassion for the simple reason that there are certain facets in his makeup that are not fully understood, by him or by others, and are not in very good control. I am also convinced that each and every one of us has something that is not managed as well as we would like. It's true for me and it's true for everyone else that I am aware of. We are all humanoids, after all.

One thing that I do find here that I have often observed, and also experienced, is a tendency for a group, or possibly a clique within a group, to "gang up" on some individual who is *perceived* as "vulnerable" or "alien" in some respect.

Group dynamics can sometimes be rather ruthless. Ask any high school student. I see some of that here. The operating principle is that the group asserts itself as the "norm" and ostracizes and "goes after" those who who seem to be "deviant" in some way.

My basic opinion, regarding this individual, is that in my limited contact I have treated him with respect, and he has treated me with respect in return. And I do appreciate that. And I think he does too. And I find that very interesting.

And for this particular individual, I am certain that the button pushers have exacerbated his particular difficulty. I see no criminal behavior here, therefore I see a lot of room for a more humane tolerance and a more cautious approach that does

not push buttons and cause loop instability. Then we will see that he has contributions to make (I have seen some of them).

This is one of "those" questions that you really can't answer.
The only way to tell which would be 'best' it to try both of them,
there are just too many variables to guess. Not much help, but
shouldn't be that hard to try them both...

Hi Cecil,

It follows that if the source presents a cumulative Z that is 1/Z of
the cumulative Load, you have a conjugate.

It is rather facile and non-productive to strip the models down to the
point to prove Thevenin's generator (being perfect) couldn't possibly,
conjunctively, match to any load.

Definitly not true. Most transmitters are designed to operate correctly into50 + j
0 ohms, therefore it is quite natural to reference the discussion to that value.
Steve's example also did the same thing.

The complex conjugate of 50 + j0 is 50 - j 0.

> There are no typically 50

Nothing is confounded. The goal of a tuner is to *transform* the complex load to 50
+j0.

It is true that the internal resistance is a "dynamic" lossless resistance, and it is true also that actual resistive tank losses modify the "net" value of internal resistance, but to claim that this process *assures* a conjugate match inside the amplifier is a "stretch" to say the least. It just simply cannot be guaranteed according to any kind of analysis that I can think of.

I am really amazed that anyone would try to force such a conclusion. What would be the motivation for it?

If an approximate match is OK, then OK, but let's spell it out. We must set the stage regarding what is exactly right and what is an acceptable approximation. We cannot be re-writing basic principles of mathematics and physics and Everitt's book to suit our own desires.

I must be missing something here. I am not an antenna guru by any
means but I have modeled a 40M Delta and a 40M dipole and the Delta
came out better by 1.8dB over the dipole. I was using Nec4Win to do
the modeling, is there a problem with this software?? I have run a 40M
verticaly oriented square loop fed in teh bottom center for a couple
of years now and it beats the pants off of any 40M dipole that I have
ever had up. In ON4UN's book, "Low Band DXing" he also mentions the
slight gain advantage of a vertical loop. Am I being duped or what??

Thanks for taking the time to help me out..

Source record: 179227

I've never seen a delta loop with gain of 2-4 dB better than a dipole in any modeling I've done, with any program. In fact, most loops I've modeled are inferior to a dipole if the tops of the antennas are at the same height. The gains are often comparable, but the loops radiate at a higher angle because of the current flowing on wires closer to the ground. This is not to say you can't come up with a loop that's better than a dipole at the same maximum height -- I'm just saying that they're often worse.

As I understand it, NEC4WIN uses MININEC for calculations. Consequently, it can't be trusted if your model has horizontal wires lower than about 0.2 wavelength. It would also somewhat overestimate the resonant frequency of something with the geometry of a delta loop, but that wouldn't be important in this case. Otherwise, its results should be just fine.

For more about these and other limitations of MININEC see "MININEC: The Other Edge of the Sword", QST, Feb. 1991.

Like all modeling programs and methods, NEC also has limitations -- but different ones. You'll see many of these described in the EZNEC manual.

Maybe he could use a stub to tune. I don't use those that often, but they can be real handy. I can match almost anything to any line with the right stub. One problem I could see using the offset feed method, is a slight loss of balance. This while no big deal on normal size dipoles, might cause slight problems with a dual stick setup. Or at least as far as the pattern. He might be better off keeping the antenna equal on each side and using the stub. He would also need a 1:1 balun of some type. Could be as simple as a choke. I've got a puter program that will calculate the stubs. Makes it a snap. MK

Bill Sabin, W0IHY wrote:
"Most transmitters are designed to operate correctly into 50 + j0 ohms, therefore it is quite natural to reference the discussion to that value."

Yes. The surge impedance of the coax most used with transmitters is the cause of specifying their performance into a 50-ohm resistor. The transmitter should be obliged to meet its specifications regardless of its internal impedance, if any or if near infinity. Maximum power transfer may not be required of a transmitter to deliver specified performance.

Naturally, an operator would not want to squander power in the feedline or matching networks.

If anything confounds me, it is the discussion of what amounts to an isolation pad to impedance match a transmitter to its antenna. If matching circuits are low loss, maximum power transfer makes sense. Broadcasters measure antenna impedance and install the conjugate matching network required to seamlessly connect the antenna with the feedline so that no power is reflected at the junction. The broadcaster can`t afford to waste any power.

Best regards, Richard Harrison, KB5WZI

Thread:

For the record...

On this NG I represent myself personally and no one else.

I use my personal email account which is paid for from my own personal funds to access and post to the NG. I use no corporate or company funds to support my NG activity.

I have only an amateur interest in this NG. This interest arrises from the perspective of one of my life long hobbies, amateur radio, in which I have participated for over 40 years. I have been an ARRL member for almost as long, and I am also a QCWA member with a 40 year pin.

I was born and raised in Canada, but now live, work and play in the USA and I am now proud to be a citizen of the USA. In case anyone doubts my amateur status and interests on this NG and for the record my call sign record is: VE1AEX, VE3DZK, VE2POB, AB4BC, and now K1PO.

Peter K1PO

PS:

OK, OK just to satisfy Chip's curiosity...

I have to confess to a certain commercial interest in antennas, but I would never allow that to taint my amateur interests and my objectivity. And so... I'll confess my commercial connection, by blood, to the antenna business here and now.

My brother Sam is not an amateur, rather he is a professional with a Ph.D. a graduate of Cambridge whose dissertation was in the field of electromagnetics and antennas. He lives and works in Europe and is also an adjunct at the Technion in Tel Aviv, where he sometimes collaborates with Lempel and Ziv. He is a member of the IEE and is a professional engineer. He left Canada to study in Europe and never returned. He does however support the rest of the Brackett family with the proceeds of his antenna company in Europe.

For you see, my brother Sam Brackett, owns and operates a successful antenna manufacturing company in Southern Europe located near the ETSI headquarters in Sophia-Antoplis.

Sam has recently patented a novel kind of antenna system which utilizes a honeycomb like physical structure based upon a famous pseudo-random sequence known as the Weiner Numbers. [Cfr. Dr. Norbert Weiner, MIT SP RPT, 17, 1944.

These "Weiner" antennas appear similar to fractal antennas but are based upon a set of pseudo-random functions first presented by Dr. Weiner, and form a new basis for electromagnetic theory which utilizes the eigenfunctions of the Weiner functionals to establish an orthonormal basis in the vector space over which the antennas are projected.

Because of the simplicity of the Weiner number generator, these antennas exhibit optimally compact time-space ambiguity functions which prove that they are superior to the common fractals as originally defined by Mandlebrot. These Weiner generator functionals exhibit compact support over specified time-space-frequency domains that allow direct synthesis to a global minimum, similar to signal design using the prolate spheroidal wave functions, and do not require dumb pattern searches or the use of GA methods to attempt to mitigate dumb searches stopping on local minima in the pattern searches.

Sam's new Weiner antennas should be available on the marketplace soon. He has found a unique method of manufacturing which uses the natural mechanical strength inherent in the designs because of Steiltjes measure of the Weiner number generator, whereas the mechanical robustness of fractal antennas emanates from the Rieman measure of the fractal geometry and as such is fatally flawed. According to Sam!

I hope this clarifies my commercial interests in antennas and should reassure all NG readers of my objectivity in critiqueing the pontifications of one N1IR!

I pretty much noticed the same thing on 75m. I tried a horizontal loop hoping for a good NVIS type deal for close in coverage. It didn't really play as planned. Here anyway....I found the overall performance of a dipole and the horizontal loop at the same height almost identical. If anything, I prefered the dipole. I found for overall general use, the turnstile beat both of them. It's still my favorite general use 80m antenna. I've used those off and on since the mid 80's. Work great. MK

Good news. I discovered that Comet makes (although no one seems to stock)
an SO-239 to NMO mount adapter (intended to allow NMO antenna to be used on
SO-239 mounts). I also discovered that Valor makes an NMO to 3/8 x 24
adapter. Two adapters and viola! This is probably going to be the easiest
and strongest solution. I do like the other ideas, especially the antenna
switch idea, and might try them after all. I have archived these posts for
future reference. For now, though, I am going to try these adapers.
Thanks to everyone for their thoughtful posts.
See you on 20 meters!

Well, I did say "almost" automatically. :-) Since the load-line is
dynamic, why is it surprising that it automatically adjusts itself
to the load? The dissipative source resistance is somewhat out of
our control but how about the non-dissipative dynamic source
resistance being effected by the load?

> I am really amazed that anyone would try to force such a conclusion. What would be
> the motivation for it?

No force required. I don't know how to keep a dynamic load-line from
being affected and effected by the load, do you? If the load-line
happens to correspond to the designed-for load-line seems maximum
power transfer is almost automatically guaranteed.

> If an approximate match is OK, then OK, but let's spell it out. We must set the stage
> regarding what is exactly right and what is an acceptable approximation. We cannot
> be re-writing basic principles of mathematics and physics and Everitt's book to suit
> our own desires.

I've only asked the question about ten times now. Exactly how close to a
conjugate match must we come to call it a conjugate match? If the load
pulling measurement results in a calculated source of 56 ohms into a 50
ohm load, is that close enough?

Wayne, I am not an expert here, but, I have an opinion, based on a
lifetime of Engineering experience- The approach you desribe is not
likely to hold up for very long, especially in the climate you
mention.(4 ft frost line)
1. Conduit is not meant to carry much load- it is designed to be easily
bent, to conform to the path needed for wiring. It is intended to carry
very light loads, but to provide impact protection to electrical wire.
2. most "house" wire is soft and is easily stretched. In your climate-
the load in winter is expected to get pretty high, due to ice formation.
expect some stretch.
Why not spend just a little more and get better poles, and better wire?
it will hold up lots longer.

Good luck- Bill-W4BSG

Wayne,
Don't waste your time. Electrical conduit was never made to
withstand the types of strees an antenna mast has to withstand.
Conduit is never used for a structural member.
I understand the budget part, but invest in a couple of good
antenna masts that were made to do the job. Even so, at 30 feet,
plan to guy the masts (maybe more than one level). The old
saying, "It's better to over-do to start with than to re-do later",
really is true.

>
>Bill W0IYH

Hi Bill,

The problem I was attending was the presentation of a definition of Conjugation by example instead of by meaning.

Certainly the definition can be reduced to your examples, and as dry as they are they serve little in the way of illustration. Take for instance, one of our non-engineering correspondents speculated the need for negative resistance to meet the definition. That one is so far off the scope because it conforms to a slavish shorthand (incorrectly applied) for the operation of conjugation.

The Complex Conjugate is defined as having the same magnitude as ï¿½ but having the negative
angle of ï¿½ such that:
if ï¿½ = a + jb
then ï¿½* = a - jb

I won't argue your assumptions for the source Z being 50 ï¿½j 0 in the sense that there is a
real part. I won't even argue that this real part is not close. It is a specific value, per specification supplied by the manufacturer; but even here I've seen qualifications as to how accurate that value is.

The point is that the artificial constraint to 50 Ohms will paint you into a rhetorical corner. For one, this valuation is correct for one power level only. It may hold at other levels by virtue of the buffering capacity of the output filter, but the manufacturer neither specifies that it will, nor warrants how well. This is not an issue of Conjugation luckily, but it becomes a practical problem when Cecil wants to measure it. You may have a rig that performs quite differently than his when you both run half power. You may even have rigs from the same manufacturer and still suffer validation problems.

As for
>Nothing is confounded. The goal of a tuner is to *transform* the complex load to 50
>+j0.
I would amend that to say:
The goal of a tuner is to *transform* the complex load to the complex source.

This is perfectly within the characteristics of the garden variety tuner and conjugation has no mandate to render a purely resistive solution. Aside from the problems of metering, the average tuner is a symmetric device and antenna and transmitter connections can be freely swapped.

That complex source *may be* 50 Ohms. Frequently that complex source *may not be* 50 Ohms. My own rigs present between 35 and 70 Ohms depending on band and power level. With the R fluctuating, the output filter is no longer matched and is probably casting reactance into these valuations. Thus we have a complex source with one of my examples possibly exhibiting a Z of 35 - j12 Ohms (contrived I will admit, but a distinct possibility).

50 Ohms as a source Z is convenient, attainable, but hardly the logical link pin in any conjugation based argument and worse, presents logistical nightmares in experimental verification. It is much simpler to report the data and let the math shake out the conjugate.

Guys, a compromise between glass-mounted and exterior-mounted antennas is this: Take the end of your feedline and remove about 19 inches of the outer cover; at that point separate the inner conductor from the copper braid and run them opposite to each other and perpendicular to the feedline, taping them to your rear window:

```
inner cond. copper braid
-------------||--------------
||
||
|| coax feedline
||
||
```

It's nothing but a 2m dipole made entirely from the last 19 inches of your feedline, taped to your car's back window. If the horizontal orientation bothers you, run the two legs at a 45 degree angle from the vertex (where the conductors separate) with that point taped to the base of the window:

```
\ /
\ /
\ /
\ /
\/
||
||
||
```

No muss, no fuss, no damage to the car, and much better results than the glass-mounted "dummy load."

It makes a fine indoor antenna at home, too; mount it as a vertical dipole taped to a window.

Hi John,

We both drive the same rigs. The shell on back is fibreglass (if it
isn't the newest of models - mine's an '88) and you could conceivably
build a radiator inside, beneath the shell for maximum "invisibility."
A wild notion of mine would be to delta or gamma match the roll bar!
I have two mounts on both rear quarter panels installed underneath the
shell and on top of the lip. One is currently sporting a full-size 6M
whip, so there's no sport in that (be careful tho' because the
tailgate down or up makes a significant difference). I haven't used
the other one yet, but was planning something for HF (once I get an HF
rig inside - not a simple thing in these small cabs).

Another thought is that the SGC tuner would easily ride inside and
perform just as well with the lead snaking out through a "small" hole.
However, from the tenor of your note, SGC doesn't sound like a
purchase option though, and I figure you probably have one of the
newer models of the 4-Runner that blasts away my presumptions :-(

Message-ID: <st4ond8f19da41@corp.supernews.com>
Source record: 179274

Here's an idea if you just don't want to run another cable from the trunk to the radio. Install another antenna mount, a 3/8 x 24, on the trunk lip and cut both coax cables from the antenna mounts and install PL259's on all the ends. Then buy a two position antenna switch, and mount it in the trunk so you can select either the PL259 mount or the 3/8 X 24 mount to connect to the radio.

I will address this issue relative to Walt's and my QEX letters. I may suggest a few exercises to the students at home who are really interested in the subject.

It is a given that a "conjugate match" exists when maximum power is being delivered from a fixed source to an adjustable load. The first point to make is that we must identify an arbitrary location in the transmission line system where the conjugate match is defined to occur. For now, let's define it at the output terminals of the transmitter. When the load

impedance connected at the terminals of the transmitter is adjusted such that maximum power is being delivered from the transmitter to the load, the load impedance will be the conjugate of the transmitter's output impedance. By definition, for maximum power transfer, the impedance looking to the right from our arbitrary point must be the complex conjugate of the impedance looking to the left from the same point. Note that one impedance is determined looking in the forward direction and the other is determined looking in the rearward direction. The forward impedance would be measured by connecting an analyzer to the transmission line input and the rearward impedance would be measured by connecting an analyzer to the transmitter output terminals (not recommended unless you don't need that analyzer anymore). Calculation of the impedances is performed in a similar manner.

In a lossless transmission line system, a conjugate match established at one point in the system established a conjugate match at every point in the system.

In a transmission line system with loss, a conjugate match can be established at any point in the system. However, establishing a conjugate match at any one point in a lossy system does not establish a conjugate match at every point in the system.

Now, let's relate these concepts to the discussion of the lossy T-network. The issue is simply the following, does creating an impedance match at the input terminals of the lossy T-network immediately establish the existence of a conjugate match at the T-network output. Stated another way, does establishing an impedance match at the T-network input create the condition of maximum power transfer to the load connected at the T-network output?

Establishing a ZO impedance match at the T-network input will establish a conjugate match at the T-network input if the impedance seen looking rearward towards the transmitter from the T-network input is also ZO. However, a conjugate match will not be established at the T-network output. To establish a conjugate match at the T-network output, the impedance looking forward from the T-network output must be the complex conjugate of the impedance seen looking rearward into the T-network output. A conjugate match can be established at the T-network output through component value adjustment but an impedance match will not exist at the T-network input. Proof of these statements
requires more time than available in this post. I would be pleased to send info to anyone interested or provide it in a later post.

The implication of the statements in the preceding paragraph is that more power can be delivered to a load at the lossy T-network output with a mismatch at
the T-network input than with a match at the T-network input. This can be verified through measurement or calculation. Connect a somewhat high SWR load to your
tuner and establish an impedance match at the network input. (A load with an R less than Zo works best as more loss will develop in the tuner). Measure the forward and reflected power at the tuner output. The power delivered to the transmission line is Pforward - Preflected. Now adjust the

tuner components for maximum forward power in the transmission line. In this case more power is delivered to the transmission line (maximum power hence the CM) but an impedance match will not exist at the tuner input. This measurement may be difficult depending on the losses in the tuner (the lossier the better for illustration) and the resolution of your power meter. Mathematical proof of these concepts will be provided in a later post.

As for the impedance calculations described in the QEX letters, here's a simple
exercise:

Assume the load at the tuner output is 150 + j50 ohms. Now design your own lossy T-network circuit (pick some reasonably low Q's) to achieve a 50 ohm matched input impedance at the T-network input. Next, use the method described by Walt to determine the T-network output impedance. It should calculate the output impedance to be 150 - j50 ohms. Next, adjust the component values (keeping Q constant) to change the input impedance to any other purely resistive value. An impedance match will no longer exist but now calculate the T-network output impedance using Walt's methods.

73,
Steve VE9SRB

In the interest of open exchange, anyone in contact with Walt can forward this message to him.

3538. Re: Query on Rooftop vertical on Apt. building?

From: Will <gwelfster@earthlink.net>
Message-ID: <39D26159.FAD0BBC3@earthlink.net>
Source record: 179276

Indeed, AEA is out of business, and the Isoloop is no longer available. MFJ does make a similar small transmitting loop, but at nearly $400 for the 40-15 version, it is pricey (there is a German firm that sells them also, "DAK" or "DAL" I think, and they look much better made, and better specs in nearly all respects, but even more $$$) and since John has the run of the rooftops (like many streets in Brooklyn, the buildings are all connected), a full-size, "conventional" antenna is in order.

I have homebrewed two magnetic loops, and while their performance is quite remarkable relative to their size, they present several fairly severe compromises that anyone with adequate space need not accept. In addition to being touchy to tune, as has already been mentioned, their efficiency on 40 and 30 is low, on the order of 12-15%, and you are restricted to an absolute maximum of 150W in transmitting (using any of the commercial available models). The real problem on 7 MHz and below is the 3 dB bandwidth of the antenna. MFJ does not publish much info on this subject, but I found my clone to clip SSB signals on both TX and RX, as would be expected, even though I "overbuilt" my loop [3M diameter, 1.5" *copper*tubing, higher voltage cap, less minumum and more maximum capacitance]. Getting a one-meter diameter loop to pass 3 KHz of signal below 14 MHz is impossible, saving perhaps the use of unmanageably wide diameter conductors (12"?).

The second of my two loops had a diamter of 3.5 meters, and did load on 80, with much broader SWR BW on 40 than the first one, on the order of 10 KHz, which was essentially a homebrew clone of the MFJ (using a homebrew "trombone-style" variable capacitor with a 40 mil PTFE dielectric, instead of the butterfly air vairable MFJ uses, and constructed of copper reefer tubing instead of aluminum). Because of the PTFE dielectric, both loop caps had breakdown voltages, in theory, of about 40 kV. I never measured them, but managed to feed 500W CW into the larger model on 80M with no signs of arcing or puncture, over a period of several months. This larger loop was constructed in an attempt to have fun and learn the limits of the small loop design, but at more than 10 feet across, much of the main advantage of magloops, small size, was lost.

Unless you have space restrictions, or demand instant portability, the small transmitting loop is not a great choice as a principle HF antenna. It is still fun to play with, and to hear the comments of the people you work on it, but when you have support structures, and literally hundreds of linear feet to play with, a conventional vertical or dipole, or other wire antenna, is the better bet.

I think it is a rather extreme interpretation to say that the QEX editorial policy on fractal antennas, if one does exist, is an attempt to prevent a new technology from reaching market. Such conspiracies are largely impossible to maintain, if the technology being supressed *really* offers the degree of improvement and benefit that is claimed for it, especially when design and construction info is so readily distributed via the internet, and in the case of fractal-shaped antennas, homebrewing presents no particular problems. However, it seems more reasonable to me that the editors of QEX are just being skeptical, as they should be of a newer idea. I do find fractal antenna theory intriguing, and hope the theory someday bears *full* fruit. having more hams experiment with fractal designs would certainly help to find out whether fractal antennas have a real permanent place in mainstream use, especially at HF.

In the field of antennas in particular, there has been so much hucksterism and snake-oil sold over the years (can you say CFA?), that editors who wish to maintain the integrity of their publication might understandably be reluctant to publish any articles on the subject that aren't accompanied by *scrupulous* documentation and repeatable results. That is pretty much the standard of any scholarly and/or peer-reviewed journal, even if the audience is principly hobbyists. Perhaps the author of this promised fractal antenna article has satisified these prudent requirements, and thus they are willing to publish it. Take a look at a recent issue of "73" magazine if you have any doubts what can happen to a magazine that doesn't maintain reasonably rigorous standards in accepting and publishing technical articles.

What issue will the fractal article appear in? I don't regularly buy QEX, but I'd like to at least sneak a peek at it at HRO when it comes out.

While a horizontal loop, being omnidirectional, will by definition have less gain in the direction of the main lobes of a dipole, if the loop is mounted in the vertical plane, the pattern should be nearly the same as the dipole, and exhibit 2-4 dB gain over the dipole. Since the Super Loops that RadioWorks sells are marketed as vertical loops, I think that ought to be the basis for comparison. If you want cover all of 3500-4000 KHz, a fullwave loop ought to be a bit easier to match and a bit more efficient as well.

I don't claim the intellectual capability to get in the middle of a discussion with the likes of Walt, Steve, Kevin, et al.

Lacking such capability, I often rely on "crutches", in this case I will use ARRL Radio Designer (ARD). I will assume Ulrich Rohde and his cohorts implemented the correct mathematics and will proceed with the following, that I offer without comments other than those necesary to explain my method.

Here is the netlist that describes a (C-L-C) t-network network "tuner." The values below are for ideal components, i.e, the component Qs are infinite.

```
*************************************************
* Define some values that will be allowed to change
* during optimization.

BLK
C1:?10PF 278.109PF 500PF?
C2:?10PF 482.114PF 600PF?
L1:?.2UH 6.78066UH 26UH?
END

*************************************************
* Create an output load for the network using the
* impedance defined at the end of the file.

BLK
IMP 1 0 IMP_TERM
LOAD:1POR 1
END

*************************************************
* Define the netlist for the t-network.
```

```
BLK
CAP 1 2 C=C1
IND 2 0 L=l1
CAP 2 3 C=C2
T_NET: 2POR 1 3
END

*****************************************************
* Connect the load to the t-network output and
* define the whole thing as a one port. Looking
* into this will show what the load on the
* transmitter will be. The optimizer will adjust
* the network to minimize the VSWR here.

BLK
T_NET 1 2
LOAD 2
I_MATCH: 1POR 1
END

*****************************************************
* This block is used to look into the t-network
* output port and see the impedance when the
* input is terminated in 50 ohm. If there is a
* true conjugate match then this should be the
* complex conjugate of the load impedance defined
* below.

BLK
RES 1 0 R=50
T_NET 1 2
REV: 1POR 2
END

*****************************************************
* This defines a frequency sweep

FREQ
STEP 3.7MHZ 3.8MHZ 25KHZ
END

*****************************************************
* Here the optimizer is set up to adjust the network
* for best input match while also minimizing
* insertion loss.

OPT

* The following section sets the input match goal

I_MATCH
F=3.75MHZ
MS11=-40db LT w=10
```

```
* The following ensures that a "bad" set of values
* that hurt insertion loss is not selected.
* The port impedances are set to match source and load.

T_NET
Z1=50 0 Z2=IMP_TERM
F=3.75MHZ
MS21 = 0DB W=1

END

************************************************
* Here define the characteristics of the load R +jX

DATA
IMP_TERM:IMP
500 0
END
```

As defined, the t-network is set up to present a 50 lom load to a transmitter while it is terminated in a purely resistive 500 ohm load. This is an entirely arbritary but useful example.

For the case of lossless components, the following table describes the results of analysis after optimization:

```
Freq RZ11 IZ11 VSWR MS21 RZ11 IZ11
MHz ohm ohm dB ohm ohm
LOAD LOAD I_MATCH T_NET REV REV

3.700 500.0 0.0 1.08:1 -0.01 495.3 38.9
3.725 500.0 0.0 1.04:1 -0.00 498.6 19.3
3.750 500.0 0.0 1.00:1 -0.00 500.3 -0.1
3.775 500.0 0.0 1.04:1 -0.00 500.3 -19.2
3.800 500.0 0.0 1.08:1 -0.01 498.7 -37.8
```

The loss in the system is zero and the impedance looking back into the network is the conjugate of the load Z.

If portions of the circuit are changed as follows, non-ideal components are used and there is now loss in the system:

```
BLK
C1:?10PF 303.183PF 500PF?
C2:?10PF 594.289PF 600PF?
L1:?.2UH 6.41898UH 26UH?
END

************************************************
* Define the netlist for the t-network with lossy components

BLK
CAP 1 2 C=C1 Q2=500 F=4MHZ
IND 2 0 L=l1 Q2=20 F=4MHZ
CAP 2 3 C=C2 Q2=500 F=4MHZ
```

```
T_NET: 2POR 1 3
END

************************************************

The results after optimization are as follows:

Freq RZ11 IZ11 VSWR MS21 RZ11 IZ11
MHz ohm ohm dB ohm ohm
LOAD LOAD I_MATCH T_NET REV REV

3.700 500.0 0.0 1.07:1 -0.72 381.3 -9.3
3.725 500.0 0.0 1.04:1 -0.71 381.2 -20.9
3.750 500.0 0.0 1.02:1 -0.70 380.4 -32.3
3.775 500.0 0.0 1.05:1 -0.70 378.8 -43.3
3.800 500.0 0.0 1.08:1 -0.70 376.5 -54.0

Summary (according to ARD):

When lossy components are used, there is--no surprise--loss in the network and
the view looking back into the output of the network no longer is the conjugate
of the load Z.

Respectfully submitted

Wes Stewart, N7WS

Granted, but 10 will get you 100 that inide of ten years Linux
development will have that OS in a very competitive position in relation
to Windows. Apple's to-be-released-any-moment OS X is built on Linux,
and in anticipation of that event Apple's stock and sales have already
jumped over 15%. If that trend continues, and there are a number of
reasons to expect that is will, and more and more developers jump on the
Linux bandwagon, we may finally be able to shake off the Windows chains
we have labored under (oh brother, is that an understatement!) in the
not so distant future. Still, we haven't heard back from Mr. Bill, who
may yet find some way to co-opt or buy out the Linux world! Captialism
works great, at least until a few people manage to acquire too much capital!

Actually, you must have been considering upgrading for *50* years. The
Class-A license hasn't existed since about 1950. :-)

> One system I saw recently on the SGC

I believe it has the whip running up through the center of the helical.
On a bang-for-bucks ratio, the SGC system is one of the worst choices
you can make. Take a look at my web page for results of actual 75m
mobile antenna measurements. Although the Bugcatchers and Screwdrivers
are best, sounds like the Hustler series might meet your requirements.

> match at any one point in a lossy system does not establish a conjugate
> match at every point in the system.

So there can exist a conjugate match from Point-A out to the antenna but not
from Point-A back to the transmitter? I suspect it can be proven that a
perfect conjugate match cannot exist in the real world any more than a
perfect yardstick can exist in the real world. After all, the conjugate
matching theorum assumes no resistance at all in those 4-terminal networks.

> A conjugate
> match can be established at the T-network output through component value
> adjustment but an impedance match will not exist at the T-network input.

But this may be akin to saying that the yardstick at the NBS is not exactly
a yard long. Exactly how far can a real world Conjugate Match deviate
from an ideal Conjugate Match and still be called a Conjugate Match. Are
we talking 0.000001% accuracy or 10% accuracy?

Unfortunately working DX contests on 80 or 160 does not require the same skill set as someone running a 10M contest.

I, personally, don't think Yuri has sufficient skills to beat me.

Well, this is just a guess, but...

Roy volunteered to put various antenna files on his web site.

Roy is in Washington.

You will notice there is no directly identifiable person or organization in
the "press release".

Hi All,

Wow!

Looks like I'm going to Disneyland!

I would consult an attorney in regards to this slander and defamation, but then I would miss the joke. To paraphrase Andy Warhol: "everyone will be infamous on the internet for 15 microseconds."

Instead I will bide a while until such time as Fragile Antenna's assets are well established and can afford me a comfortable, early retirement - but that's the Joke! Assets? This is dreaming in technicolor and surround sound.

This announcement at Yahoo alone is enough to plunge the stock of any company down the toilet. Gad, it sounds so desperate and pleading. But this approach is very nearly the same as I've pointed out elsewhere, it seems the best line of defense is to damn your own design (company) to put a pox on the replica (reviewer).

For those who are curious about the genesis of this, they may visit my page at:
http://www.qsl.net/kb7qhc/antenna/fractal/n1ir/k2/index.htm
or perform a search of DejaNews with the term "k2" or "Flying H."

Here you can observe how these designs pour power into the ground to optimize a successful launch angle at 10 degrees with -4.7dBi (+/- 3 dB). And the good news is that this is the best gain you will obtain! The price is a little stiff though - variations of several inches in elevation can drive the SWR through the roof. Want to experience the

thrill of these without building them? A handful of mud in each ear would come to a close approximation at those other angles (it also helps with F/B so that those annoying back seat drivers or noisy patrons at the movies don't upset you).

So now, where's all the bleeding heart types who offer that redemption of the savage is a noble prospect? I won't count on you fellows for my defense fund, but I will save a spot at the gallows for you (bring your dancing shoes). ;->

>Indeed, AEA is out of business, and the Isoloop is no longer available.
>MFJ does make a similar small transmitting loop, but at nearly $400 for
>the 40-15 version, it is pricey.

I have seen the MFJ unit close up and I do not believe that it is overpriced. The critical part of the loop's performance is the capacitor and their's has large plates welded to the loop. They have also made continual improvements to the control unit. The Lab kept the Product Review unit, and it has been banging around and loaned to different HQ staff without incident for years.

>I have homebrewed two magnetic loops, and while their performance is
>quite remarkable relative to their size, they present several fairly
>severe compromises that anyone with adequate space need not accept.

The published efficiency spec for the AEA unit was, if memory serves, 78% on 20 meters. I ran an EZNEC model and made some assumptions about capacitor Q and believe this to be the case. As a small antenna, it lacks the extra dB or so of "gain" that one gets with a half-wave dipole, but I am not sure that, if properly built for low loss, the compromises are all that severe. The main compromise is that it has to be tuned for relatively small frequency excursions.

> their efficiency on 40 and 30 is low, on the order of 12-15%,

That sounds lower than I recall for the 30 meter model I ran; I think I was seeing about 40% or so. On 40 meters, it will be lower, but the efficiency of a loaded 8-foot whip is in the range of 10-15% on 40 meters, too.

> and you are restricted to an absolute maximum of 150W in transmitting

A real limit, but one that encompasses the vast majority of HF rigs. Those who have the limited space requirements are not apt to want to run any more than 100 W anyway, for RFI reasons.

> MFJ does not publish much info on this subject, but I found my clone to clip
> SSB signals on both TX and RX, as would be expected

I can just barely imagine this to be possible on 40 meters, but even then, I have to wonder how the Q could be that high. If the antenna is touted to be inefficient, the Q is not high.

>10 KHz, which was essentially a homebrew clone of the MFJ (using a
>homebrew "trombone-style" variable capacitor with a 40 mil PTFE
>dielectric, instead of the butterfly air vairable MFJ uses,

I have to ask whether this will have nearly as high a Q as an air-variable with plates welded to the radiating loop? On 40 meters, any degradation in the Q of the capacitor will make a big difference in the loop performance.

After 11 years here, I am leaving Arizona on Friday morning. Why? Ultimately because life here has degraded badly, and nobody is a citizen anymore, everyone is just a "taxpayer." Everything here is justified or ruled out here on the basis of what "taxpayers" want, rather than what is good or fair public policy.

Arizona is dead last of 50 states in school funding (the "Sun City" voting bloc has seen to that, having *never* come in above 10% in favor of *any* funding increases or other improvements to education or child healthcare; why should they? They already raised *their* kids elsewhere, thank you), child poverty, urban environmental quality, domestic violence, gerrymandering, safety licensure [locksmiths, asbestos removal companies, certain health care providers need no screening or licensure], proper zoning and development regulation [leapfrogging so much that it takes 30 minutes for emergency response to the newer, farther out subdivisons, taxing already strained police/fire/EMS resources], workplace safety, and urban traffic safety [worst traffic fatality rate bar none]; it is first in the nation in terms of accidental gun deaths of minors, tuberculosis (ironic, huh?), failing schools [AIMS test? talk about your "unfunded mandates"!], juvenile health (only one of 4 states to have a measles epidemic post-1960, as recently as 1988), red light runners, average miles-per-day commute, is under [by 5-to-1 over the nearest runner-up] the most court orders of *any* state to reform and improve schools, jails, hospitals, streets & highways, mines, use of public lands, and awarding of government contracts, and the legislature is the biggest collection of kooks and unreconstructed niggling rabble rousers and paranoiacs of anywhere I can think of outside of Louisiana. On top of that, it is just to damn hot, and every 10K new red-tile roofed houses they put in raises the average annualized temperature by almost a quarter of a segree fahrenheit, and the relative humidity by over half a percent (pools lawns). I shudder to think of the quality of the lives of people living hear in 20 years on less that $150K/year!

The AZ State House wanted to secede from the Union a couple of years ago, over a threat by the Feds to withhold highway funding because the state was defying court orders and the rules every other state has to follow, to reduce air pollution. Secede? I say Arizona ought to be expelled from the Union! Arizona seems to want to be its own country, so be it! Let the laughing stock of the nation fend for itself. For god's sake, if you value your quality of life and your health and safety, *DO NOT* even consider moving hear, unless you are A) retired, B) rich, and C)choose a remote rural part of the state, out of reach of the moron-cabal of Maricopa-Pima county and the State Guvmint.

To those that have the demo version, I will add that, IMHO, the "full" version, DOS or Windows, is well worth the asking price. That 20-seg limitation will get you every time. In using NEC, and then EZNEC, to play with all sorts of antennas on the computer screen, I have learned things about antennas that are NOT found in the text books. At least spring for the DOS version; you will NOT be disappointed!

> now calculate the T-network output impedance using Walt's methods.

The thing that is consistently (conveniently) ignored is that even if the tuner is completely lossless, a conjugate match at the output of the tuner cannot be achieved *unless* conjugate match at the output of the PA is also achieved. In other words (in the above example), unless the output impedance of the PA is 50 ohms pure resistance. The validity of even a "theoretical" conjugate match in the system is based on this crucial premise.

That 50 ohms output resistance is achieved in certain carefully rigged experiments, or if the PA is designed specifically to have a 50 ohm output resistance, for example by the use of negative feedback. In 95% or more of PA's used for amplitude-varying radio communication (AM, SSB, PSK31 etc) there is no assurance of this whatsoever in vac tube or xistor PAs.

I suppose there are cases where conjugate match is important. But as a bare minimum you had better be damned sure the PA output Z is 50 + j0 ohms. And that does not happen by decree or wishful thinking.

I have seen all of the stultifying, mind-numbing rhetoric that tries to convince me that the output Z is, in fact, "assured" to be 50 ohms resistive. It is junk science.

That's no surprise, Wes, but is it close enough? Exactly how much of a
deviation from perfection can be tolerated? If it is within 0.00001%
of a conjugate match, is that good enough? What about 1%, 5%, 10%?

I don't think that's so, Will. Most of the single vertical loops
that I have modeled showed slightly less gain and slightly wider
beamwidths than dipoles for the same maximum height.

3566. Tower installation publications? Anyone?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-27 00:00:00 UTC
From: Zoran Brlecic <zbrlecic@earthlink.net>
Message-ID: <39D27C58.6F71A792@earthlink.net>
Source record: 179304

First of all, I would like to apologize for off-topic posting on this ng which clearly deals exclusively with something called "fractal" antennas. I personally don't have nearly enough expertise to get involved in the discussions about lawsuits, death threats, name calling and other fractal stuff, so until the time I grow up, I'll refrain from posting again.

However, I do need some help which is tower-related (and as such, having nothing to do with antennas, fractal and nonfractal, whatsoever). This winter I'll be installing my first tower ever, and I'm looking for any publication that deal with the issue. Namely, guying, grounding, tips and tricks, and so on... And yes, yes, I do know about the tower-talk reflector, but I don't feel like subscribing to e-mail discussion groups. So - does anyone know if there is a book, brochure, website, anything out there dealing with tower installations? I did not find jackshi... I mean, anything, in the QST and CQ bookstores.

Thanks and 73

>mounted antenna, at least in comparison with most modern European cars.

The SUVs suck! I tried to put beefed up Hustler on the trailer hitch on GMC Yukon Denali and performance went down considerably as compared to my "radiomobile" - 72 Buick LeSabre where the antenna is mounted on the fender and that old beauty is one mother of a ground plane.
The best think would be to put something on the roof (if it is metal), but then you are limited with height and is clumsy to take it down (quick disconnect). Hustler with "splitter" and three resonators would work very well. SGC is the worst system with tuner at the base.

There is one train of thought that a conjugate match is achieved
almost automatically by the combination of Rs and the non-dissipative
load line inside the amplifier. In other words, the source impedance
includes both the non-dissipative load line and the dissipative losses.
Thus an amplifier can have an efficiency greater than 50% while
maintaining a conjugate match, just as an antenna can have an
efficiency greater than 50% when conjugately matched.

Hi Cecil,

Accuracy has no part in the discussion really. Rather it is a
question of definition (and dontcherdare pull out that IEEE
dictionary!), or even the proper assignment of variables.

The measure of RF Power by amateurs cannot be said to be any more
accurate than 20% without a considerable investment in equipment,
training, and NIST certification. Basically much the same could be
said of amateur editing.

So the argument has nothing to do with reality, huh? No matter
how close to a perfect conjugate match you are, you can never
prove it has been achieved. After all, proving a conjugate match
depends upon measurements with built in inaccuracies.

Hi All,

This above is a rather strained definition for Conjugate. Conjugation
is simply the complex, inverse value of the load with respect to the
source (or vice-versa). The presumption of a 50 Ohm requirement is an
artificial constraint in anticipation of arguments that might follow,
illustrating a typical (blackboard) case. There are no typically 50
Ohm antennas and as such nearly any antenna is compounded with
reactance to achieve this value or other Resistive value is allowed to
accumulate SWR as it is deemed inconsequential (the 37 Ohm perfect
Monopole or the 73 Ohm perfect Dipole). Of course either of these may
manifest 50 Ohms raw to the system, but that is a consequence of
proximity to ground and confounds the statement above.

The issue of the existence of a conjugate match is of secondary interest to me in these wave reflection discussions. In discussing it, I try to emphasis the points you make above. Of primary concern to me in these discussions (not that any of it really matters) is the concepts related to how the impedance match is achieved as a function of wave reflections within the transmission line system, how rearward traveling power is delivered back into a tuner or transmitter's output stages (assuming no tuning circuit), and how voltages and power combine in the steady state. Clearly it is an academic discussion but some are interested in the topic so why not discuss it? Learning is always beneficial.

Take care.

Have you considered an FT-100 + ATAS-100 combination?

You could get around the 'advertising' by removing the antenna and fitting a blanking cover when leaving the car. Which you'd probably want to consider anyway as the ATAS-100 costs £250.

Using this antenna also means a tuner is not required.

I'm awaiting delivery of an ATAS-100, so can't at this moment give you an indication of it's performance, but the documentation mentions that you can manually tune the antenna to bands not covered in it's specifications by using the controls on the radio.

Both the FT-100 and FT-847 are compatible with this antenna.

Have fun, de M5WJF

> --
> http://web.wt.net/~nm5k

I put up an 80 meter loop skywire using 4 30 ft top rail poles that
worked out very well. I started by pounding four steel fence posts into
the ground at the proper points. I then put two clamps at each fence
post so they would be handy at the time the poles were walked up into
the vertical posision. The poles were made ready with guy rope and
stakes pounded for use with the ground end of the guy ropes. Also
pulleys were installed at the tops of the poles and rope attached. The
poles were then walked up and clamped to the fence posts when vertical.
You will need a calm day to do this alone. After the poles are clamped
to the fence post you may then guy the pole to the ground stakes. After
all the poles are up and guyed down it's easy to pull up the antenna
wire.

Hi CAM,

Thanks for your input but I'm sure I was older than 3 when I was first licensed ;)
> Actually, you must have been considering upgrading for *50* years
Here in UK we do still have Class A = any amateur band operation (and I'm sure you know that really) whereas my license is Class B = above 30Mhz. Just the Morse test to pass.
I think it was 1963 when the Class B was first made available, prior to that the only option was to pass the exam and the Morse test before being granted the ticket. I sometimes think that system was better, at least there was no chance to become an amateur operator and 'do the Morse someday soon....'
We all know how easily the excuses appear when a little effort is required, hi.
I wasn't thinking of actually buying the SGC kit - just picking up ideas prior to building something, but I will check your site and also pick up some Hustler info.

Thanks again, John G8OZH

Richard,

Thanks for the reply. Unfortunately we drive the same rigs in name only. The 4-Runner over here was an all steel estate car version (like a 95/100 scale Land Cruiser) which offers a better ground plane from the full size metal roof but looses the easy option of mounting the tuner internally. I'm quite keen to mount on the roof as I believe the bumper and tow hitch types may suffer from some shielding or coupling effects due to proximity to the bodywork. If I'm looking for minimum visual impact I think I am already compromising performance considerably without looking for even more trouble ;)

The resonated roll bar sounds interesting - my wife drives a HiLux pick up with a roll bar made of 2.5 inch tubing.....

You are right about not purchasing the SGC kit - I'm just fishing around in many areas for ideas and while the commercial offerings may not be the best performers around they must have something going for them. Don't they? Really? Oh! Well to hell with 'em then....

73, John G8OZH

Yuri says:
> The best think would be to put something on the roof (if it is metal),
but
then you are limited with height and is clumsy to take it down

Yep, metal roof, 6 feet off the road and quite large. It could be a problem with height and will certainly be a challenge to take down quickly, but an 'easy' location would surely compromise performance further. Who said life was meant to be simple....

Your comment noted re the location of the tuning elements at the base of the SGC system but this arrangement does help to keep the visual impact to a minimum. Another vote for the Hustler though.

Thanks Yuri, 73, John G8OZH

>Have you considered an FT-100 + ATAS-100 combination?

In a word - No. I already have the radio (IC706) and I had not heard of the ATAS 100 until today. I see it is mentioned in another posting to this NG also. Another possible solution for me to investigate although I was originally intending to build my own antenna after picking sufficient brains!

Thanks for the response - and keep 'em coming.

Thanks, Roy; now you know why they won't let me edit anything. I was assuming that "gain" with no reference could be presumed to be gain over isotropic. I think it is all pretty clear now. I understood it before; now I know how to say it better. :-)

Dan Richardson <k6mhe@arrl.net> wrote:

> Really admire your responding. I only wish you could respond outside
> you role at ARRL HQ, but understand your choosing not to do so.

Hi, Danny,

It is not even a question of my being permitted to respond outside my role at ARRL HQ; it is a question of my not being able to respond with what I believe to be accurate information. There certainly are questions about whether conjugate matching has been applied correctly in all cases (amplifier loading, for example). But, that notwithstanding, the articles are still a really good, albeit lenghty, explanation of SWR. IMHO, it is a question of technical, not ego, issues.

I have not gone through all of the math and steps so I really can't say that I fully understand all of the principles that are on the plate, so rather than offer what I would not feel certain of, I stick to what I know. I don't mind having a bit of egg on my face once in a while from a technical faux pas, but if I do, it is because I honestly misunderstood something. But I do not want to offer speculation instead of fact, especially coming from the ARRL Lab. Zack is more qualified than I to address it, and he did, in the July/August QEX (URL previously posted).

Heck, those who have seen me post know that, if I feel comfortable that I know the answer, I am more than willing to post about a wide range of ARRL topics, including, in some cases, my perceptions of the sense of the ARRL Board. :-) There are times when discretion is required in my public participation (publications plans, in-progress work with Board committees, etc.) but this isn't one of them. Sorry, but it really isn't that Ed knows something that he is not telling. :-)

As posted several times on this NG---

I suggest you start with Hohlfeld and Cohen:"Self Similarity and the Geometric Requirements for Frequency Independence in Antennae", published in the peer reviewed journal FRACTALS last year.

Note that I made, and many people took advantage of, a free offer on this NG for copies of said article.

It is still possible to get copies of the article --to fractal antenna member subscribers.

To join:

fractalantenna-subscribe@egroups.com

Also note that even in the early publications from 1995 and 1996, I made a point of providing explanations for how fractal element antennas work. Indeed, I have discussed them many,many times on this NG. Now I continue to answer the relevant questions on a moderated list with archive storage.

I have found that the most handy and the best way to help those with a bona fide interest.

You are certainly correct that, in general, I no longer answer such questions on this NG. I do , on occasion, respond, but IMHO, you would do best to pose any questions you have on the fractal antenna reflector.

If you believe I tarnished your reputation, you are more
>than
>welcome to repost anything I said yourself. I wouldn't waste my time.

If the silly thing looks like the Diamond ones, unscrew the present one, and go
to Radio Sack and look for the SO-239 base & 3/8 Threaded mount on the top, and
screw that in to replace it. It's simpler than looking for an adapter if I'm
correct, and if not, well at least I'm not telling you to waste money, since
I'm telling you to unscrew the present adapter on the mount.

Hi John,

My buddy John (AA7UJ) uses the SGC for his big Ford (he also has a 5
band diplexer for VHF-UHF). We have the advantage that SGC is located
here in town. I can't recommend it myself because I don't make the
big bucks he does as a salesman. :-<

> I have a question about all these models. How are they verified
>as to their results?

At different heights, the results are different. If you place the
antennas in freespace, that is where the gain advantage is maximum
when changing from a dipole to loop. The maximum change is about 2 dB
under ideal conditions.

If you place the antenna as was discussed (close to the ground) the
loop can actually have loss. At best, it has virtually no gain.

As you move the antenna to different heights you'll see the gain
difference goes through gyrations ranging from almost no gain to
almost the same as the freespace difference.

Loops do not have "2 dB gain" at all heights, and the do not offer 2dB
gain at any height over dipole elements when multiple elements are
involved.

They don't do anything at all in low horizontal loops.

The transmitter was designed to work into a 50 ohm load. If you supply that load you are in business. In my years at Rockwell Collins or as W0IYH I can't remember one time when I was concerned about Zout or conjugate match of a PA. I do know that a few others were concerned in special applications. TV and other special transmitters worry about output impedance. They don't want re-reflections at the xmtr. Circulators are sometimes used to absorb reflections.

Let me repeat something that I have said before (all of this stuff is deja vous all over again every year or so). If you start at the antenna terminals and look only in the forward direction and work backwards toward the transmitter, and get everything tuned up and working as you work toward the transmitter, and never look backward, then at some point you arrive at the transmitter output terminal and everything is FB OM and you don't know, and couldn't care less what the output impedance of the PA is. You dip and load, set the meters where you want them, look at distortion products on the spectrum analyzer, and you go to lunch. You are finished, and you don't have a clue about conjugate match.

Unless it is really important.

> the internal power dissipation is in each case? (ha)

That's an efficiency question. If an amplifier has been designed
for maximum efficiency, who cares what the output impedance really
is if it is looking into a Z0-match, i.e. no reflections? Seems to
me the Z0-match has all the positive characteristics of a conjugate
match without the excess emotional baggage. That's why I talk about
Z0-matches achieved at the input of antenna tuners instead of
conjugate matches achieved at the output. The Z0-match point is where
the reflections are neutralized and their energy joins the forward waves
such that forward power equals generated power plus reflected power.

It doesn't look like much of a finger error; I just ran it again here at
work (NEC-4 engine) and got Z=81.7+j0.1 for a resonant 6 M half-wave dipole
8 feet over average ground.

> A possible answer came in E-mail. It said: "Note that minimum SWR
> is not always consistent with resonance." And Ed's post talked about
> 1:8 to 1 at resonance - it didn't say minimum swr.

The SWR did not change much when I went above or below 50.2 MHz, the
frequency for which I designed the antenna. It remained near 1.6:1, in this
case.

> Bottom line - I can get the swr below 1:2 to 1 on all of these antennas.

Something is sure going on. :-) The following graph shows how the
resistive component of the EZNEC model varied with height above ground.
See:

http://www.arrl.org/~ehare/temp/6mdip.jpg

> Does EZNEC insist that a 50 mhz dipole (8' above ground but
> otherwise clear of influence of nearby objects) at *minimum* swr
> will be close to 1:8 to 1 ? If so, it is wrong.

In running it here over average ground, it says 1.6:1 is what you should get
at 8 feet. I don't recall my ground parameters when I ran it at home.

> Another question: I've always thought that a dipole exhibited minimum
> swr close to resonance - again, assuming it is in the clear of objects
> other than ground.

That is my modeling and real-world experience.

Post a file here the refutes the objective evidence presented in:
http://www.qsl.net/kb7qhc/antenna/fractal/n1ir/k2/index.htm

Are you even capable of a clear description matching:
http://www.qsl.net/kb7qhc/antenna/fractal/n1ir/k2/index.htm

Explain why this model is not correct:
http://www.qsl.net/kb7qhc/antenna/fractal/n1ir/k2/index.htm

This has nothing to do with copyright which has NOT
been violated in any way so please, Mr Cohen, why is this model incorrect?
http://www.qsl.net/kb7qhc/antenna/fractal/n1ir/k2/index.htm

We are waiting to see an answer as concise and definitive as:
http://www.qsl.net/kb7qhc/antenna/fractal/n1ir/k2/index.htm

Hi OM,

I will trust your numbers and add Amen!

But the "yardstick" is still in Paris.

Of note, when you mention the wavelengths as standard, many standards are wavelength based. Standard Capacitors are ultimatley based on a coaxial design, whose dimension in the axial direction (sliding one tube into another tube separated by an insulator) is set and measured using laser interferometry. The measure of Time is based on a specific wavelength of Cesium. Time being defined, Frequency follows.

The Volt is defined by a quantum effect, the Josephson Junction, and hence Resistance and Current follow. I can't tell you how sad it is to see Standard Cells, the premier Voltage Standard in the world for 8 decades, being kicked around in junk boxes at swap meets.

Hi OM,

You lookin' to get your information from an authoritative source?

Or could you get by with the ramblings of a fool (certified highly erroneous by well known and widely respected Doctors of Learning) such as myself (BA English)?

Mea Culpa - Veno Vat

Fractals. They come in three flavors: Big and small. What color do you want?

So much for theory.

Big means gain. Small means - uh - well small! Geez.

So much for benefits.

Of course much more can be said and much has - to no great positive effect.

440 MHz? You can go small (isn't this small enough?) and find a nice match with performance on par with the antenna it is replacing. Or you can go Big and find gain (small print: some models require additional assembly to match to Hi-Z, speak to your dealer about our wonderful assortment of options (your mileage may suffer causing tread separation)).

To boil it all down, fractals relative to either a monopole or dipole exhibit higher gains on average (in the so-called DX angles); wide matches (unlike trapped designs); and for the Big guns flat response across bands. The downside? They're - uh - fractals! Geez.

I hope I proved to be less than coy :->

100w-->--51.5 ohm coax--x--1/4WL 300 ohm line--51.5 ohm load

P+
--->100w--->----x---->200w----->-----+---51.5 ohms
Pg ^ | 100 w
| | Prad
+----<--100w--<------+
P-

In fixed format, values chosen to make P- = P+/2
100 watts generated, 100 watts reflected, 200 watts forward at the
Z0-match point. It certainly appears that the reflected energy can
be considered to have reversed direction and joined the generated
energy on a trip back to the antenna. There is no tuner and the
Z0-match is a point. There are no reflections to the left of the
Z0-match point and reflections exist to the right of the Z0-match
point.

> I told Walt that I would not debate these particular points on usenet again.

Why? It's a simple concept. Pg+P- = P+. 100+100=200. Why are you
afraid to discuss it in public?

> Would you prefer to take this topic offline?

Nope! That takes all the fun out of it. :-)

3616. Re: new antenna help (using MFJ analyzer)

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-28 00:00:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <39D4256B.4035B2EB@eznec.com>
Source record: 179101

I have very high confidence in the ability of EZNEC and similar programs to predict the SWR of an antenna as simple as a dipole. Its ability to do so has been verified on many occasions.

Accurate measurement of input impedance and SWR is much more difficult than calculation, and subject to many more sources of error. These include, but are by no means limited to:

-- Stray shunt and/or series reactance in the measurement instrument
-- Calibration of the measurement instrument
-- Common mode feedline current

Also, factors may be present which aren't included in the model, such as:

-- Capacitance of loops at antenna ends
-- Capacitance of end insulators
-- Reactance at the feedline connection point
-- The effect of nearby objects

I've measured "50 ohm" feedline at over 60 ohms of impedance; this isn't uncommon. The impedance transformation caused by an incorrect impedance will result in an incorrect SWR indication.

Finally, there's the matter of feedline loss. A load which would indicate 1.8:1 SWR with lossless feedline will show 1.6:1 if the line has only one dB of loss, or 1.44:1 if the line has 2 dB of loss. And this is assuming that the "50 ohm" line is really 50 ohms.

The factors not included in the model can frequently be included if known, and the line loss and impedance accounted for, in which case the program will give an accurate inducation of the SWR which would be read with an accurate meter. But you do have to account for these if you want a truly accurate result from the program. Garbage in, garbage out.

Compared to accounting for and controlling all these factors, calculation is a cinch.

>his writings became persona non grata in League publications, according to some
>of the same sources.

Hi Dick and Ed,

I always picture it as an "tire problem" on a car.

A writer is either fully running or not. Either everything said flys
right through without question, or everything said stops.

Maxwell's tire was punctured because a few people concluded the
conjugate match explaination was no good. Some of the original
arguments were so flawed they were silly, like those concluding
conjugate match efficiency could only be 50%!

Instead of patching the flat tire, or having the problem looked at by
disinterested outsiders, the easiest solution appears to always be
junking the car by smashing it all up......no matter how well
everything else works.

Even if the issue of a conjugate match is and will always be
unaccepted by some, even if opinions always remain divided, it is
tragic to take it to a level where we are all deprived of a what was
one of the most useful books around on antennas and transmission
lines. Especially when the whole snit was over what happens inside a
PA.

No one has proven any of the real-world suggestions misleading, the
entire beef is that dreaded "conjugate match" idea and the damn
non-linear part of the system...the PA.

You obviously mean a resistance which is large compared to the generator source impedance. Seems to me, if the generator source impedance was zero, *ALL* the power would be transferred to the load. :-)

I guess he knows the overall needs of the publication; it is unfortunate that the article you wanted to write is not the one that he needed, but these things happen.

> I get asked to write such articles every 4 months or so by someone. I am
> committed to two at the moment.

Well, that should certainly help ensure that info on the fractal antenna design is available. You have been at this for several years, so at one every few months, there should be a lot of good info. I look forward to reading the bibliography that your site mentions as coming soon.

> At least Steve Ford asked me to write up the FQY for QST...that was

> But also a bit deceptive.

> He was fishing without any true sense of interest INHO. My sense was it
was
> really meant for (requested for) QEX .

I generally would not base a public assessment that someone had been deceptive in his dealings with me on a "sense." Steve is tasked with filling QST every month, not QEX, and of late, the QST editors have very much wished they had more articles to choose from. If Steve took the time to ask you to write it up, it was because he wanted it. I am a bit curious about why you feel that Steve wanted a specific antenna construction article for QEX but also felt that Doug didn't want an article about a specific antenna? It sounds more like a communications breakdown, not a deception.

> I was asked to write for QEX before also. Rudy Severns wanted me to write

I don't know what all the factors were that ended up in the discontinuance of the Reflections book, Dan. But I rather expect that if the sales volume was high, the book would not have been discontinued.

What "politics" would be more important than techncial issues in a technical publication? If the editors chose to use what they felt was better material, in what way would that be "political?" What political advantage do you believe that ARRL would have gained by not publishing the material?

> Would you care to comment?

Most comments I could make would be outside the scope of my role at ARRL HQ, Dan, but there was no objection to the ARRL Tech Info Service reprinting Walt's QST series on the ARRL Web pages.

>
> Best regards, Richard Harrison, KB5WZI
>

I'm not sure why you would consider my statements junk science. My statement are based on scientific fact (IMHO). In any general transmission line system, establishing an impedance match at one point in a system does not, in and of itself, establish a conjuagte match at the same point or at another point in the system. They are unrelated in that regard. I did not mean to imply that they can never exist together.

Let's consider establishing an impedance match and a conjugate match at the same point. For example, the tuner input. If you establish an impedance match at the tuner input, a conjugate match will exist at the tuner input if and only if the impedance seen looking rearward towards the transmitter is also equal to ZO. This requires the output impedance seen looking rearward into the transmitter to be ZO.

Let's consider the tuner input and output. In the special case of the lossless tuner, establishing an impedance match at the tuner input will result a conjugate match being established at the tuner output. This relationship requires two things. 1) the tuner be lossless and 2) that the impedance seen looking rearward from the tuner input towards the transmitter also be ZO.

In the case of a lossy tuner, establishing an impedance match at the tuner input will never result in a conjugate match (maximum power transfer to the load at the tuner output) being established at the tuner output. I have a very very simple example that I will post later tonight that should (will) prove this.

Hi again Richard:

My statements were based on the following:

For a conjugate match to exist, an impedance match is not necessarily
required.

When an impedance match exists, it does not necessarily mean that a
conjugate match is established.

Clearly, there are always special cases where the two will exist together.
These are the basis of my statement that the two are "unrelated".

Hi,
I ran 3 coax runs to my attic.

Coax #1 has: 20 and 10 meter dipoles on them
Coax #2 has 30 and 15 meter dipoles on them.
Coax #3 has: a 40 meter dipole on it, I used 2 dipole shorteners
from Spi-Ro Mfg. Overall length 37'

My attic is about 35' long, for 30 and 40 I wrap the wire across
the end of the attic to the rafters on the side, let remainder dangle
down.

Much cheaper than the IsoLoop (or MFJ clone) and the IsoTron

BTW, the dipoles don't seem to interfere with each other - I don't
use a tuner for the 20/10 or 30/15 dipoles (actually I do when I
operate 18mhz or 12 mhz from the 20/10 meter dipoles...work into Europe
daily on 18 mhz).

For 40 I use a tuner for the CW portion of the band, as it
resonates around 7.260.

The one who is in a position to explain the decisions about the content of ARRL books is Joel Kleinman, N1BKE, the Book Team Supervisor. Are you telling us that he did not respond when you asked him for an explanation?

> 1. I hear many hams are looking for the book but can't find it.

The book was based a lot on the original series of QST article, "Another Look at Reflections." The articles are still published on the ARRL CD ROMs and are available for download at:

http://www.arrl.org/tis/info/pdf/Reflect.pdf

Does the fact that ARRL still makes the articles available change your mind about the conspiracy theory, Dick?

I asked a similar question a couple of months ago and I was refered to
an article on the ARRL database comparing those two antennas with some
other small antennas. If you're an ARRL member it's in the review
section on the ARRL web site. If you're not a member send me an email
and I'll send you a copy of the review.
Based on the review however I decided not to buy or try either of those
antennas but to stick with my wire dipole.

When a Z0-match has been established such that there are no reflections
on the transmitter's Z0 transmission line, for the same amount of power,
all the voltages, currents, and phases are identical to a conjugate match.

It mounts to a standard SO-238 type mount. It needs no special wiring other than the normal coax feedline, all control signals are sent from the radio via the coax. As far as mounts, it needs to be fairly strong, and it is very important that the mount presents a really good ground to the antenna. This antenna works great IF it has a good ground system. Without a good ground, or with a less than optimum ground system the performance will be disappointing.

It could well be that it wasn't "political" at all, Cecil. The "politics"
do not seem to have gotten in the way of my reprinting the article series on
the TIS web pages.

Speaking of which, we are going to add Zack Lau's recent QEX piece on the
conjugate match. Until it is up on the "official" page, here it is
temporarily: (enjoy)

Your statement is correct when the transmitter output impedance is also ZO.
This is consistent with this statements in my previous posts.

If the transmitter source impedance (ZS) is not equal to ZO, more power is
delivered to load having an impedance ZS* with reflections on the line than
is to a load of ZO with no reflections on the line.

I am currently putting up my "first tower ever", a used 50 foot
Tri-Ex crankup. It is a very interesting experience. Tomorrow
I pour the cement for the footer.

Probably the best information was obtained from the guy that
I bought the tower from. You could probably go down to a
local club and ask someone to expound on his/her experiences.

Beyond that, I found the installation instructions, from the
tower manufacturer, to be very helpful. My tower doesn't require
guy wires.

Another very good source turned out to be the 1999 ARRL Antenna Handbook. They particularly cover guying and grounding information. It may not be the most complete collection of information, but it's better than nothing.

How big of a tower are you planning on putting up? I have a friend that is also installing a tower, but his is a 70 foot chankup. His doesn't require guy wires either.

Well, Good luck on your new tower. By this time tomorrow I'll be watching my cement harden.

Martin K7MEM

Hello,

Looking to install a ATAS 100 antenna on a 1997 Jeep Cherokee. This Cherokee has a metal hatch. Which mount, besides a mag-mount, to use for the ATAS 100 ?

Thanks for any suggestions...

Jason

Ed Hare, W1RFI wrote:
"Not necessarily. If one has gain, one must have directivity (so far, so good), but it is entirely possible to have directivity but no gain." (Not so good)

Ed Hare must mean no gain with respect to some reference when losses are included with the antenna`s directional gain.

Ed Laport said "---the loop antenna giving a figure-of-eight pattern---." and "The wave, or Beverage, antenna has been for many years the principal low-frequency directive antenna---."

Elsewhere, Ed Laport says directivity and gain are the same thing, resulting from constructive or destructive phase combinations caused by the antenna elements.

So, directivity and gain are as inseparable as E and H in the far field. You can`t have one without the other. The fact that loss may absorb power from a Beverage or loopstick does not eliminate its gain, though it may affect the output total from a system.

I think it is misleading to say: "it is entirely possible to have directivity without gain", especially when so many have a demonstrated misunderstanding of the connection between directivity and gain.

Best regards, Richard Harrison, KB5WZI

> in the system.

I would like to present two examples that illustrate the important ideas about impedance match and conjugate match. Please take a piece of paper and draw the diagrams that I will describe.

Draw on the paper a box, a PA with a 50+j0 ohm output impedance.

Connect to the PA a tuner. The tuner box consists of a single reactance, an ideal conventional transformer with a certain turns ratio and *possibly* a

single resistor that we will place (arbitrarily, but it can be anywhere) in series with the output terminal. At a single frequency *any* tuner can be correctly represented by these three components. All reactances are combined into a single reactance and all resistances are combined into a single resistance that accounts for all losses.

The load is 30+j40 ohms. We want the input impedance of the tuner to be 50+j0 ohms.

Assume the internal resistor is 0 ohms (the tuner is lossless). Now do the following things inside the tuner:
a) Put a -j40 ohm reactance in series with the output terminal.
b) Place a transformer with a turns ratio of 1.29:1at the input (hi-Z side toward the PA.

The PA now sees 50+j0 ohms. Consider what conjugate match means: If we stand at the tuner output and look toward the load we see 30+j40 ohms. If we turn around and look the other way into the tuner we see 30-j40 ohms. The PA 50 ohms, transformed down to 30 ohms by the transformer, in series with -j40 ohms, is the conjugate of the load.

Now let the PA output impedance be other than 50+j0 ohms, say 60+j0. If we calculate the impedance looking into the output of the tuner it is now 36-j40 ohms. No longer the conjugate of the load. But the PA still sees 50+j0, looking into the tuner input.

Conclusion: The output Z of the lossless tuner is not the conjugate of the load *unless* the PA output impedance is 50 ohms.

Next: Insert a 10 ohm resistor inside the tuner (its loss resistance) in series with the -j40 ohm reactance. Now we must modify the turns ratio to 1.12:1 so that the PA will still see 50+j0 ohms. In other words (10+30) times the square of 1.12 is 50 ohms (the load reactance is still cancelled out).

Now, looking back into the tuner output we see 50 divided 1.12 squared +10 =50 -j40 ohms. This is *not* the conjugate of the 30+j40 load.

We do not have a conjugate match at the output of the tuner, but the PA still sees 50+j0. We could modify the tuner to get a conjugate matched output but its input will not be 50+j0 ohms.

Conclusions:

(1) A conjugate match at the tuner output and a 50 ohm tuner input can be achieved simultaneously if and only if the PA is 50 ohms.

(2) If the tuner has loss, a conjugate match at the tuner output and a 50 ohm tuner input cannot be achieved simultaneously.

The Conjugate Match Theorem means exactly and precisely what it says:

"If a group of four terminal networks containing only pure reactances are arranged in tandem to connect a generator to a load, then if at any junction there is a conjugate match of impedances, there will be a conjugate match of

impedances at every other junction in the system".

We are not allowed to play any games with this. It is complete and covers all contingencies. There are no exceptions.

> included with the antenna`s directional gain.

Is that not part of the definition of directivity? From the ARRL Antenna Book, 18th edition (N6BV), Eq 5 from Chapter 2:

D = P / Pav where D is the directivity, P is the power density at its maximum point on the surface of a sphere and Pav is the average power density on the surface of the sphere. If the antenna is inefficient, both P and Pav will be reduced by the same amount, so it can still have directivity.

Gain is defined:

G = eff * D

So an inefficient antenna (ie, loopstick) can have directivity, but no gain.

"You obviously mean a resistance which is large compared to the generator source impedance."

Actually, I meant a large resistance when compared with the voltage available from the generator. The current through the resistance must then be small. If an infinite voltage is available all bets are off!

I don't know the figures so really can't offer a factual opinion, but
that said, it seems to me that I have never before, in my 45+ years in
amateur radio, seen such a clamor for copies of an "out of print"
amateur radio book that has been generated by "Reflections".

As I said before, I have formed my opinion based upon the fact that
just about everything Walter had contributed was purged from the
other ARRL publications at about the same time... The only gain I
can think of is that someone's ego was involved. It has been by
experience that is the case with most corporate & organizational
political decisions. I really don't believe that decision was made by
the ARRL as a whole, because, overall that decision was not (in my
opinion) beneficial to the ARRL nor amateur radio community.

Granted a belief is a belief and I can't "prove" anything, however,
it is based upon (questionable?) actions that I have observed.

Jeffrey,
I would recommend ferrite beads on all leads that enter and leave the amplifier, including the power (line) leads. If this doesn't work, try a balanced line filter as is used on most electronic equipment these days. You may have to put a lowpass filter on the audio output leads. Make sure the amplifier chassis is grounded. All filtering should be done at the amplifier.
Hope this helps, best wishes from ray w6fya

The "*unless* the PA output impedance is 50 ohms" statement is only specific to the condition that a conjugate match at the tuner output AND an impedance match at the tuner input both exist simultaneously. I think if you read my discussion again you may find that we do not disagree as much as I perceive you think we do. If we are interested in achieving a conjugate match we can do so regardless of the PA output impedance. We just will not have an impedance match in the system.

Change the load to 36 + j40 ohms and we now have a conjugate match at the tuner output with the PA not being 50 ohms. All consistent with the conjugate match theorem. We can still establish a conjugate match *at* the tuner output. We need to define the point in the system where we want to create the conjugate match, i.e. at the point where we define the system "load".

Yes, I think if you review my discussion you will note that I said this.

Also, if there are losses in the system, establishing a conjugate match at one point does not establish a conjugate match at everypoint. Also, establishing an impedance match at one point does not necessarily establish a conjugate match at any point.

I intend to.

Yuri has maintained, for some time, that the 10M FQY seen on the ham page of

http://www.fractenna.com

is a very poor antenna and a fraud. He even told this to a New York Times reporter in July 1999. This is despite the antenna is well documented as the best option for its size; highly efficient; very good in performance; easy to build; and reliable.

If this were true, then he would have no problem whatsoever in beating me.

But its not true; I am a very good contest operator; and I will beat the panst off of him.

FOR IMMEDIATE RELEASE:

Independent lab reports confirm that CANTENNA <tm> outperforms Fractal.

One scientist at the lab, after extensive testing, was heard to exclaim "But isn't a CANTENNA<tm> a dummy load?"

To clarify things...let us just say that yes, a CANTENNA<tm> IS a dummy load. However it has been suggested that the same term could be applied to a nocturnal emission from Chip.

3657. Re: NEC4 Model of MI2 Fractal Loop Vs ...Who Knows ??

Newsgroup: rec.radio.amateur.antenna

Source record: 179158

I disagree somewhat with both you gentlemen, although I think you're largely trying to say the same thing, and my disagreement is likely due simply to lack of precision in your statements.

I don't much like Ed's statement that an antenna can have "no gain", and at least an implication that it's possible to have no directivity. Every antenna has gain compared to something. An antenna can certainly have a negative gain relative to an isotropic source (i.e., a gain which is a negative dBi value), which is probably what Ed means.

I disagree with Richard Harrison's statement (quoting or paraphrasing LaPorte) that directivity and gain are the same thing. As Ed has pointed out, they differ by the efficiency. I don't have LaPorte, but all other references I have make this distinction; I'll be glad to give page and equation numbers if anyone is interested.

All antennas have directivity, which is simply the ratio to the maximum radiation intensity (radiated field power density) to the average radiation intensity. The directivity of an isotropic antenna is 1. All other antennas have greater directivity, and this doesn't depend on an antenna's efficiency. For example, half wave dipoles made from a perfect conductor and from an extremely lossy conductor have the same directivity (1.64).

Let's consider a 100% efficient antenna in free space. If it spreads its signal equally in all directions, its gain is 0 dBi in all directions. But only an isotropic source, by definition, has this pattern. If a 100% efficient antenna distributes its radiated power in any other way, it will have greater than 0 dBi gain in some direction(s) and less in others. Considering the "gain" to be the gain in the strongest direction, any 100% efficient antenna in free space except an isotropic source must have a positive gain relative to an isotropic source (that is, the gain is greater than 0 dBi). A 100% efficient half wave dipole, for example, has a gain in dBi of 10 * log(directivity) = 10 * log(1.64) = 2.15 dBi.

As I mentioned above, reducing the efficiency doesn't affect directivity, so a 50% efficient dipole still has a directivity of 1.64. But the gain is 3 dB less than before, or 2.15 - 3.01 = -0.86 dBi. (I used the more precise 3.01 dB so the answer would agree with the next calculation.) You can also calculate this using the relationship between directivity and gain which Ed gave, or gain in dBi = 10 * log(directivity * efficiency) = 10 * log(1.64 * 0.5) = -0.86 dBi. I'm sure this is what Ed means by an antenna with "directivity but no gain". I'd rather say it has directivity (as do all antennas), and a gain less than 0 dBi.

That is exactly what I said also, and have said many times previously. There is not a nickel's difference between your conclusions and mine. My goal was to use very simple examples to illustrate the basic principles of this entire conjugate match problem.

It's interesting how simple concepts can be smothered with rhetoric that does more to confuse than to enlighten.

>worth supporting a 10m vertical right now. 20 ft is real easy to put up,
>but 30 ft is hard for one person. You would need a helper to help pull

I can recommend this. For Field Day I built 2 phased verticals
(32' ea.) out of top rail pipe. I used 2 sections on each vertical
and another 2' piece I install at the base after it's all erected
which tightens up the guy wires. I used a 'modified 3-way set of
guys (woven nylon) at about 20': 2 each on the outer ends of the
array, and 1 vertical-to-vertical guy to make up the other 2 inside guys.
Of course, I use "FD Construction, so I would use something other
than nylon rope in a permanent installation.

It is, at least, a 2-person erection -- no more than 3.
Think it through ahead of time and it'll go up smoothly.

For the base, I'd use a technique that I use for my 40' tower:
Design a 1 or 2 feet square, HEAVY guage steel plate with a small
pipe stub welded in the center to permit the vertical to slip over.
On the other side weld 2 or 3 steel spikes (as long as you can
'handle':) and drive the sucker into the ground.
You could even lay sod over it to minimise the 'appearance'.
You're only going to use the base to keep the vertical from
sinking into the ground _and_ to keep it from sliding from
side-to-side. You use the guys to hold it up.

(For FD, I use a set of 1 foot square, thick nylon blocks which
insulate the verticals, and which I bought 'surplus' for $5 each,
and for which the U.S. Taxpayer probably paid $500 each.)

With what you are seeking, I don't see why you should'nt end up
with a 2-el phased 40M vertical in the bargin!

Let me tell you: Late on Saturday night/0'dark:30 on Sunday morning,
that antenna is MONDO! I achieve *incredible* DX-style pile-ups with

just 100W from here in the Colorado Rockies. I REALLY wish I could
put one up here at the home QTH -- maybe I could for 30M....

Ain't it just like a ham to start an antenna project with Winter
coming on? HI!HI!

Good Luck es "gud dx",
Jonesy

Actually, your jest of placing an analyzer at the transmitter output terminals is something that I have done (key-down too). The trick was to disconnect the exciter before keying down. This switches the amp into the path and the idle state Z was easily determined.

For those who mumble about feedback and such, this is the perfect test of that mechanism and the validity of their suppositions (not that I validated THEIRS but rather mine).

Of course this says nothing about the Z of the transmitter when it is actually sourcing power, but it does establish a baseline. Few in these discussions have presented any method to make such a determination, and in consequence have spilled a lot of ink (in the form of bits) speculating about possibilities.

And here we go....

This I must presume is the beginning and end of it. If we are to stick by the book, then the debate is over. And yet it seems that "by the book" is unsatisfying for some.

Here again, is a presumption that could lead to complications.

The conjugate is felt throughout the system in some form or another. The conjugate, I would challenge is not found conveniently at one connector or another. This is too facile.

When I served at the bench performing RF Power and attenuation calibration, we spoke of the Plane of the Source, the Plane of Measurement and the Plane of the Load. For this subject we might refer to the Plane of Conjugation. This is what you are referring to after a fashion. The Plane of Conjugation is not going to occur at a convenient connection, but I doubt if this matters much to your

perception of the problem.

My problem with most posting to this topic are few separate or are
aware there are many forms of matching. I see two discussed above,
the ZO (or ZL) Match and the Conjugate Match. They are not the same.
NBS established that you must choose a Basis of the match and you
cannot mix the two in determination (or discussion).

Hi Steve,

In response to the simple test you outline above, I would say that being ignorant of Walt's method, that I cannot effectively respond except by generalities. I would also point out that I made many attempts to find what Basis Walt was interested in, but he never responded. I presume this was simply my inability to effectively describe the NBS's usage of the term Basis.

I did observe in his writings though, that he freely crossed from one Basis to the other. Thus I could not accept his tenets; and even though I found that I could agree to them by parts, I could not agree to them as a whole. This problem of parts also inhabits your discussion here, and for like reason, I cannot subscribe wholly to what is said.

It seems to me that your argument must stand with the arbitrary isolation of resistances and reactances "within" the source or "within" the tuner (or load for that matter). Systems don't work by parts, that's why we (in the calibration field) refer to the various planes. Those planes are specific, as specific as your connectors, but they contain no preconceived notions of exhibiting pure or impure mathematical concepts of conjugation (there are too many variables that invalidate that presumption).

In my RF Power determinations, I flattened the line at both the source and the load. The absolute best SWR I have ever obtained was 1:1.005. So appeals to perfection are lost on me as flights of fantasy. Every System has irreducible SWR, but that does not make the measure of SWR, or the flattening of a load impossible - you simply do your best on the basis of approaching a perfect solution. If you reject the notion of this perfect solution, you are in danger of rejecting effective methods of accomplishing what you set out to do.

This problem of Conjugation is not nearly as difficult as the problem of the Uncertainty of Mismatch. I have attempted to educate this group of that problem on a couple occasions, but it was roundly rejected or thoroughly ignored (same thing really). In reality this topic is simply too difficult to observe when Power determination is dominated by inaccuracy that swamps it (most Hams do not have the resources to resolve this issue because their equipment is typically very poor - even pro's suffer for the same reason).

Forgive me for introducing yet another topic - in fact neither
actually intrude into the reality of the Ham's daily operations in any
meaningful way (until they enter a Shoot-Out).

VE9SRB wrote:
> Your statement is correct when the transmitter output impedance is also ZO.

It's also true when the transmitter output impedance is not Z0.
For the *same amount of power into the same Z0-matched line*, all the
voltages, currents, and phases outside of the transmitter will be
identical to a conjugate match. For instance:

50 ohm/100w XMTR---50 ohm coax---+---1/2WL 300 ohm line---50 ohm load

20 ohm/100w XMTR---50 ohm coax---+---1/2WL 300 ohm line---50 ohm load

Each 100w transmitter will see a 50 ohm load with no reflections. Without
knowing the output impedances of the transmitters, there is no way to
tell which is the conjugate match because all external measurements of
voltage, current, and phase yield identical results. Both transmitters
are delivering 70.7 volts at 1.4 amps. Both systems are Z0-matched.

3662. VHF/UHF Ham/Business Band?

Source record: 179163

Are most base, dual-band antennas designed for Ham radio, close enough to be used for the VHF/UHF business bands? Or should I buy an antenna designed for those bands?

Thanks,
Bill Crocker

How about a Z0-match?

Consider the two following systems:

50ohm/100w XMTR---50 ohm coax---+----1/2WL 300 ohm line-----50 ohm load

20ohm/100w XMTR---50 ohm coax---+----1/2WL 300 ohm line-----50 ohm load

Conditions external to the XMTRs are *IDENTICAL* yet one is conjugately
matched and one is not? If so, what good is a conjugate match if it causes
nothing different to occur in reality? The two systems above are Z0-matched
and, neglecting losses, that seems good enough to get the identical amounts
of power to the loads with 70.7 volts and 1.4 amps. Z0-matches seem to be
the important thing to hams, not conjugate matches.

Looking at it from that perspective, I would have to agree. I wonder what
the internal power dissipation is in each case? (ha)

I'd also be interested in how you eventually mount this antenna.

I have a Land Rover Discovery with a Watson HB770 on a door edge mounting at the top of the rear door. This is currently connected to an FT-90R.

I've bought an FT-100 and am awaiting delivery of an ATAS-100 to go with it, intending to bring the FT-90R into the shack and putting the Watson in storage.

The current door edge mount provides an excellent mechanical Earth, but it's current location may not be very practical for an ATAS-100, what with needing to drive into these height restricted car parks without having it getting knocked off the back every time.

My initial thoughts are to either move the mount to just above the rear door hinges, so that the ATAS-100 can fit under these height restrictions, but I have considered mounting on the rear bumper at the right-hand side, without obscuring the lights, but will wait until it arrives.

If you can tell me the weight and dimensions of the ATAS-100, and in particular the length of any section that is NOT flexible, along with the type of connection to the coax I'd be most appreciative.

As far as I know a mag-mount installation is not recommended for an ATAS-100 in the documentation I have for the FT-847 and FT-100.

How effective is the antenna on the bands it covers anyway (assuming you've had this antenna on a different vehicle prior to the Jeep)?

On 20 and above, the small loops acquit themselves well. I still cannot
see the advantage of spending $400 for this antenna, no matter how well
constructed, or how *near* the performance of a dipole it may be, when
for $25 in materials and a little elbow grease one can have an antenna
that requires much less fiddling (especially when browsing a band for
weaker signals), better than 95% efficiency, etc., when the space is
available. Not meaning to dis' MFJ or STAs one bit, it is just a simple
cost/benefit analysis. One thing: given the original poster's intent to
mount an antenna permanently outdoors, in a quite wet (salt air), windy,
and high air-pollution area, where corrosion can decimate an aluminum TV
antenna in 3 or 4 years, how well do you think the loop will hold up?
Not a rhetorical question at all, but I do have my doubts, giving me
another reason to suggest the $25 dipole.

I would expect different performance from the 40-15 model and the 30-10
model [better on 30M for the latter of course] ,and the basis of
comparison shouldn't be to a mobile whip--John has 200-300 linear feet
for his antenna, and can get it up about 30' above the roofline, which
is already at 120' above street level. He had intially thought of a
commerical vertical, and I tried to suggest a wire antenna, given the
large amount of space available, and the lower cost, which is important
since high winds have destroyed other verticals at his QTH. Thus,
especially if he wants to work 75 (he does) and 160 (he might), a 90%+
efficient dipole is a more advantageous choice. Walkman stereo's are
great, since you can't walk around city streets with a 200W McIntosh
amp, Thorens turntable, and 10-element Klipsch speakers. But when you
have a big living room (and the budget) which would you choose?

I don't know how small loops and restricted space antennas got mixed
into this thread, but this is not an issue for this ham. I know he has
(or did have) an amp (SB-200?) that he wanted to use on 75.

My HB loop did this, mea culpa. I really don't know what the effiecy
was, lacking more than a rudimentary FS meter, but the antenna did not
pass an SSB signal without some lopping off of audio highs, it sounded
muffled, and AM SWBC was impossible. Using Reg Edwards' rjeloop1 DOS
program, the prediction, using MFJ's published specs, is close to what I
experienced on mine, in terms of BW and EFF.

Doug is a very fine Editor. I can say correctly that his policy is to avoid being an Umpire or Referee, but rather to present opposing viewpoints, without bias. I also know that he will respond with his own viewpoints in his own way, when the schedule is appropriate. And I know that he is quite capable of doing that.

The amplifier is designed to operate into some definite and fixed value of load that does not change with signal amplitude. The one-cycle average value of tube/xistor dynamic output resistance does vary with amplitude. The problem is that there is no guarantee whatsoever that this average value is some magic number that guarantees a conjugate match.

Amplifier design is based on DC supply voltage, plate voltage excursions, plate current excursions, and output signal linearity considerations. Ordinarily, conjugate match is not a consideration at all.

Why do you use the term "travesty" here, Dick? ARRL clearly has no prejudice against Maxwell or the concepts presented in Reflections. On what basis do you conclude that the League removed the book over "protests" rather than the level of sales?

> prohibit that use.

The output resistance (call it rp) of the tube/xistor varies, sometimes quite a bit, over each cycle of RF. However, these variations are "filtered" by the tuned circuit (there always is a filter of some kind, it may just be a lowpass filter).

This variation of the instantaneous value of rp over a cycle has a harmonic spectrum, just like any other waveform. The filter respond to the fundamental component, and this is the *average* one-cycle rp at the fundamental frequency.

To that extent we can talk about a Norton/Thevenin circuit. The big problem is that as the RF signal amplitude varies with modulation the one-cycle average value of rp varies in unpredictable ways. In a "linear" amplifier the change will not be enormous because this variation is itself *one* source of nonlinearity.

The best signal to use to find rp is a two-tone signal that has the desired quality of intermodulation distortion products. That way we get average rp over a full *modulation* cycle. This is very close to a real-world value with the PA operating as the Lord intended.

>dispersed, it should merge with the noise floor of the analog spectrum
>analyzer, and not produce more than a slight degradation of the
>SNR of conventional narrowband equipment, when operated at any
>reasonable physical separation.

Let's do the math. Let's assume uniform distibution of energy within the spread, a reasonable assumption for a fast hopper or a DS SS transmitter. Let's start with a whopping 10 milliwatt SS transmitter and 8 dBi gain antennas on both ends. Let's put it on 440 MHz, with a 5 MHz spread. Let's locate it on a good hill, 1 kM away from a receiver.

Here are the results:

RESULTS:
Frequency = 440 MHz
Total transmit power = .01 watts
Transmit spread = 5 MHz
Receiver bandwidth = 1000 Hz
Transmit power in 1 Hz = -56.9897 dBm/Hz
Transmit power in 1000 Hz = -26.9897 dBm
Transmit antenna gain = 8 dBi
Receive antenna gain = 8 dBi
Distance to receiver = 1 km
Free-space pathloss = -85.31905 db
System loss (path loss +/- antenna gains) = -69.31905 dB
Total loss (path loss +/- antenna gains - spreading loss) = -106.3088 dB
Specified receive system Noise Figure = 6 dB (includes external noise)
Calculated receive system sensitivity in 1000 Hz bandwidth = -138 dBm
Received noise in receiver bandwidth = -96.30875 dBm
Received noise in receiver bandwidth = S 6
Receive system noise floor increase in dB = 41.69154 dB

> But with a reasonable separation, the energy disappears into the
>noise floor for any receiving system except one using the same
>spreading code.

At 10 kM, (admittedly difficult to obtain perfect line of site), the results are as follows. How far away do you consider "reasonable separation?"

RESULTS: 0 dBm average UWB transmit power, 100 MHz UWB BW
Receive antenna = 20 dBi

Frequency = 440 MHz
Total transmit power = .01 watts
Transmit spread = 5 MHz
Receiver bandwidth = 1000 Hz
Transmit power in 1 Hz = -56.9897 dBm/Hz
Transmit power in 1000 Hz = -26.9897 dBm
Transmit antenna gain = 8 dBi
Receive antenna gain = 8 ; dBi
Distance to receiver = 10 km
Free-space pathloss = -105.3191 db
System loss (path loss +/- antenna gains) = -89.31905 dB
Total loss (path loss +/- antenna gains - spreading loss) = -126.3088 dB
Specified receive system Noise Figure = 6 dB (includes external noise)
Calculated receive system sensitivity in 1000 Hz bandwidth = -138 dBm
Received noise in receiver bandwidth = -116.3088 dBm
Received noise in receiver bandwidth = S 2
Receive system noise floor increase in dB = 21.72057 dB

Don't get me wrong, Gary; I believe firmly that the Amateur Radio Service needs to embrace spectrally efficient techniques and do so quickly. Speeched like the recent one by Dale Hatfield better be our wakeup call. But making inaccurate statements that SS will not interfere with narrowband users is NOT going to accomplish that goal; we need to accurately understand the impact in order to effect an orderly transition from the present inefficient systems to more efficient ones. And, to preseve the diversity of the ARS, we also will need to have some separation of some modes; SS and narrowband are generally not mutually compatible.

It's late for this thread, but:

Some antenna tuners have switched inductances. I buggered a Dentron for a bit more flexibility by putting a silvered-copper shorted-ring cut from a pipe inside the inductor near the unswitched end of the coil. The ring was fitted so as to be turnable from the front panel. It took care of most of those 'between-switch-position' settings, where the VSWR was low but not low enough (for me, anyway <g>). When the ring was at 90 deg. from the inductor axis, it had minimal effect.

A stack of proper powdered toroid cores can be used to increase inductance, as well.

To simplify it even further -

The design load impedance presented to the amplifying device
is

(Peak Voltage Rating) / (Peak Current Rating) ohms

without any reference to what the internal impedance of the
device might be.

Any amateur who has ever designed his own HF PA knows that.

Check the book section of your favorite Ham dealer (AES/HRO etc). The ARRL puts out a book on Sats that shud have what you want. The simplest system is 137Mhz crossed dipoles(polar orbiters). There is also a 1691Mhz system that requires some rather expensive downconverters (Geo Sats).

I doubt Chirp is going to squat. He is full of hot air. This Newsgroup is the only people that propably saw that "Press Release". If Chirp actually followed through with every one of his threats he would be in court fulltime. We should feel sorry for him and his family.

Like others, I doubt conduit is strong enough. There's a shortage of supply houses here in the sticks so I have used pipe intended to support the upper run of chain link fence with some success. 20 ft lengths are available and it's stronger than the TV mast pipe sold by Radio Shack. Naturally YMMV

Maybe -- all depends on how much you want the person and others following the thread to know the info. I do not read every post in every thread, and I believe that most people here don't, either.

If I can restate something I said in an earlier post to help an ongoing discussion, I usually don't mind doing so. It is certainly more considerate of the others following the thread than taking several posts to convince people that they should do deja-news searches to find the original post. You are a voluminous poster, Chip, and a deja-news search can involve looking at a lot of posts. Most people will not bother and most will probably assume that if it is not important enough for you to repeat, it is not important enough to look up.

Now, if the real intent is to teach people to do research instead of asking questions, I can understand why you are choosing not to restate the point.

> And if the post is to be repeated, how many times shall it be repeated? Once? twice, infinity?

You seem to have little difficulty hesitation about repeating posts that you want to repeat. :-)

As I understand it, the tank circuit acts like a flywheel to
linearize and filter out the non-linear components, i.e. the
tank circuit becomes the linear source. This is consistent
with considering the coax output connector on a transmitter
as the black box linear source with a corresponding source
impedance that can be (indirectly) measured.

Hi Bill:

When I responded to you last night, I was thinking in the context of achieving an impedance match and a conjugate match in the system simultaneously. As I thought a bit more about it, I realized that a more general response should be provided.

>
> Bill W0IYH

In any transmission line system, a conjugate match can be established at the output of a tuner regardless of the value of the PA output impedance. In a lossless system, if one establishes a conjugate match at the tuner output, then a conjugate match is simultaneously established at the output of the PA. In a lossy system this will not be the case. For example, a conjugate match can be established at the tuner output but a conjugate match will not be established at the output of the PA. In this case, maximum power is being delivered to the load at the tuner output but maximum power is not being delivered from the PA to the system. Also, in this lossy system, if we establish a conjugate match at the output of the PA, a conjugate match will not be established at the tuner output. In this case, the PA is delivering maximum power to the system but maximum power is not being delivered to the load at the tuner output. When stating that a conjugate match exists in a transmission line system, it is also necessary to define the location at which the conjugate match is said to occur.

Now let's talk about impedance matching. Let's assume that we establish an impedance match at the output of the PA. A conjugate match will only exist at the output of the PA in this case if the output impedance of the PA is also ZO. Stated another way, establishing a conjugate match at the output of the PA will only result in an impedance match if the output impedance of the PA is ZO. This is more in line with my interpretation of your comments last night. In general, the existence of a conjugate match and an impedance match are unrelated.

This is the basis of the conjugate match theorem in transmission line systems. In a transmission line system, more power will be delivered to a load that is conjugately matched than to a load that is impedance matched. The simultaneous existence of an impedance match and a conjugate match at the output of the PA requires the PA output impedance to be ZO.

It is simply incorrect to state that establishing an impedance match at one point in a system simultaneously creates a conjugate match at another point in the system.

73,
Steve, VE9SRB

3695. Re: Part 15 interference on 2.4 GHz? Re: Best antenna for 2.4 Ghz???

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-28 00:00:00 UTC
From: hasan schiers <schiers@netins.net>
Message-ID: <8qvl0h$gm7ml$1@ID-52642.news.cis.dfn.de>
Source record: 179209

Hi Ed et al,

Well, I have the 2.4 gig wireless internet stuff going. I have a couple of observations and an antenna question or two:

The system is an Orinico card with a flat panel kind of antenna which I'll discuss later. The antenna is fed with 50' of LMR 400. This is the PART 15 unlicensed equipment that has been discussed on this NG recently.

With respect to interference:

1. I detect no interference to or from my 2.4 gig video/audio transmitter/rx combo for feeding video and audio from a DBS sat receiver downstairs to the upstairs. The 2.4 gig rx ant is no more than 10' from the wireless inet antenna.

2. I detect no interference from the standard microwave oven to the wireless internet. (This same oven puts video bars and audio hum on the 2.4 gig video/audio tx/rx combo referred to above.)

3. I detect no interference from my 2m/70cm (50w out, 20' antenna separation).

4. I detect no interference from my 100w 30m vertical signal (base of GP is one ft fm wireless internet antenna)

5. I detect no inteference from my other hf ops with a Carolina Windom up 40' that is about 75' from the wireless internet antenna. I have not checked this with my 500 w amp running yet.

I say I get no obvious interference because I can monitor both the base noise level in dBm and signal level in dBm as well as S/N in dBm with the software provided with the card. I can even graph it over a specified time period. I can't induce any kind of fluctuation in the signal level with any of the devices noted above.

Throughput: I am seeing anything from 100 K bps to 400 K bps...the network is not exactly stable at this point. The RF side is stable, but the provider seems to be having "shakedown problems". My last 28 mb dowload averaged 170 Kbps.

Now...on to the antenna questions: (the antenna is a passive device, no preamps or down converters)

1. The existing antenna is a flat panel that is about 5 inches wide, 10 inches tall and 1/2 inch thick. It is mounted Horizontally. That leads me to think it is vertically polarized..maybe an array of dipoles in front of a reflector? Its stated gain is 15 dBi. (By horizontal I mean the 10 inch

length is parallel to the ground), Is it vertically polarized?

2. I have found a replacement antenna designed for exactly the same kind of service that is 39 inches wide...it is a screened reflector dish with stated gain of 24 dBi. It's 3 dB beamwidth is stated at 8 degrees. Is there any reason to assume that simply replacing one antenna with the other will not produce an improved S/N of at least 9 dB? (It might even be better due to the high directivity of the larger antenna)

The antenna can be seen at :
http://www.hyperlink.cc/antenna2400.htm

Model HG2424G

3. What is the attenuation per 100' of LMR 400 coax at 2.4 gig?

My current noise floor is about -95 dBm and my signal level is about -82 dBm.
With the new antenna, I should expect a signal level of -73 dBm...which would be quite an improvement and the noise floor might drop too?

Why am I considering this? Well....the software (as well as the installer) says I have a "marginal" signal level. I have about 13 dB S/N and they would like at least 16 dB and preferably 20 dB. While the systems seems to work well (aside from them not having their internet act together yet), I would like to see the multi-color bar graph S-Meter (and NO IT AIN'T 6 dB per S unit!) go from high yellow to "in the green", especially considering things that might happen to degrade the path. (It's 3.6 miles, but through some trees at various places along the path)

If I have analyzed this correctly, I should get a S/N of 22 dB with the new antenna, which would be exactly what I was looking for. Am I assuming too much or missing something obvious?

I expect to see some 3 to 5 dB improvement in the next month if I do nothing at all, due to the leaves coming off the trees....but that is not something I can rely on.

I would appreciate anyone's observations about the antenna situation and hope that the information regarding my interference to/from Part 15 devices and my ham radio equipment has been useful.

You, Sir, are an outrageous statement, and your toy-tennas for which you steadfastedly refuse to provide any cogent explanation, instead petulantly referring anyone who asks to a non-existant website "explanation" to search in vain for something -anything!- that would confirm that they are anything more than some fancifully decorated version of longstanding concepts, are even more outrageous. I concluded long ago that any time spent on you and your "invention" is time wasted. If you believe I tarnished your reputation, you are more than welcome to repost anything I said yourself. I wouldn't waste my time.

That may be clear to you, Ed but it "clearly" is not clear to many others. The original
complaint resulted in the book being pulled and discontinued, based on sources both here on rraa and other places. The original complainant whose name and callsign I don't recall, wrote criticisms in QST, as I recall. Shortly, Walt and his writings became persona non grata in League publications, according to some of the same sources.
If this is untrue, its past time for the League to end their silence on the matter and explain.This wouldn't be the first time controversies have been merely swept under the rug, rather than beng worked out to a *best result for ham radio* by the League.

> On what basis do you
> conclude that the League removed the book over "protests" rather than the level
> of sales?\

1. I hear many hams are looking for the book but can't find it.2 . I have had a number of them try to purchase my copy which is NOT for sale-
I don't even dare loan it out for fear it won't make it home.
3. Same as in the first paragraph above- the rumor mill which states that it has been pulled from publication due to criticisms by a Collins engineer, and that another magazine is considering resurrecting it under another label. If all this is not factual, I'd very much appreciate a full disclosure by the Leage on exactly what happened and why. If they don't find enough of a market to continue to publish it, they could easily release if for republication by someone who DID see one.

Reg Edwards wrote:
"To simplify it even further- The design load impedance presented to the amplifying device is (Peak Voltage Rating) / (Peak Current Rating) ohms, without any reference to what the internal impedance of the device might be."

Exactly.

No power is delivered to a short circuit because there is no voltage drop across the short. No power is delivered to an open circuit because there is no current through an open circuit.

If a tiny resistance loads a generator, a tiny power is delivered to the tiny resistance because there is a tiny voltage developed across the resistance.

If a large resistance loads a generator, a tiny power is delivered to the large resistance because the current through the large rsistance is tiny.

At some value between a short and an open there is a load resistance which permits maximum power to be extracted from the generator (the transmitter) and delivered to that load resistance. This is proven to be a load resistance which is equal to the generator`s internal resistance. If we have an a-c generator (the transmitter), the reactance (if any) in the circuit must be neutralized to get maximum power transfer. Reactance is neutralized by application of an equal amount of the opposite type of reactance (its conjugate). Or we can say we have corrected the power factor. Or we can say we have tuned the circuit to resonance.

In fact, we have reduced the a-c matching problem to the d-c maximum power transfer problem by eliminating the reactance in the circuit.

There should be no dispute that maximum power transfer is only possible when the source and load impedances have the same resistance and the circuit reactance adds to zero.

The long lasting disputes which appeared in this newsgroup in the past became: "Can a radio transmitter match a load?". Some transmitters just generate short pulses for tuned circuits to shape into sine waves, while others are linear by design.

No consensus was reached despite a near record number of postings, and likely can`t be reached as long as there is so much conflicting expert testimony. Amateurs are likely to only agree to some extent when most "experts" have written comments which echo each other on the subject of transmitter load matching.

Best regards, Richard Harrison, KB5WZI

Ed,

If I am to assume by your statements that the decision to remove
"Reflections" from publication was due to level of sales then I'll ask
you this question.

Why were Walter's writings, which were many, deleted from the ARRL
Antenna Book and ARRL Handbook at about the same time? It seems to me,
and I think some others on the news group, that such actions certainly
appear to be more political than technical.

Would you care to comment?

3704. IsoLoop and IsoTron antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-28 00:00:00 UTC
From: wa2bfw@my-deja.com
Message-ID: <8qvs5l$9ir$1@nnrp1.deja.com>
Source record: 179218

Since relocating out here to Calif. I'm going to have to go with an attic antenna for the time being. I'm leaning towards an AEA or MFJ IsoLoop for 10-30 and the IsoTron for 40/80. I've got some questions and would like comments on either or both of these unique antenna designs.

First the IsoLoop:
1. Although no longer made by AEA, MFJ has picked up the slack here.. There apparently were 2 versions of the antenna, the first had a metallic band as a loop, the second (newer) model has a tubular loop. There were also variations of the control box, and LCU-1, LCU-2 and IT-1, being the first, second and autotune type. Is my information correct? Can anyone tell me the differences, pros and cons of the different variants of the antenna and the controller? From what I can tell, the key point with these antennas is to have a welded variable hi-voltage capacitor.
2. Whats the latest info on the MFJ version? have they made upgrades/improvements since AEA got out of making these?

Now the IsoTron
1. I've read good reviews about these and they seem a better solution to working 40 and 80 than the IsoLoop antenna. Does anyone have any experience with the 40/80 model that they would care to comment on?

Has anyone tried both of these antennas and been able to make a real-life comparison between the two?

I'd appreciate any comments. I'll be cross posting this ine rec.radio.amateur.antennas.

Thanks, 73

I would not argue the point you are trying to make. You are correct that in practice, close enough is more than good enough. If you operate with a good lowloss tuner, achieving a perfect conjugate match would be an unnecessary exercise. We know that it all "works" in the real world.

My interest in this topic lies in the technical discussion, and understanding the theory. The whole topic from everyone's perspective has always been a theoretical discussion. With this in mind, the discussion should be fine. I think that since it is a technical discussion, the correct points should be presented and understood (that said, I accept that we disagree as to what is correct).

Hi Wes,

The measure of RF Power and RF Attenuation are worlds apart in both
accuracy and resolution. A Simpson 260, load and a simple detection
circuit (1N914 and cap) with a step attenuator will resolve very well
and provide good accuracy - but only as good as the step attenuator.
Even here there is no need of NIST, but training yes.

Measure that appeals to ratios is probably the best approach to any
problem that requires accuracy as it is generally easy for even the
amateur to accomplish the calibration. This level of accuracy can
approach 1/100ths of a percent depending upon what is being
calibrated. I have employed these techniques out to 15 places.

Measure of RF Power is extremely difficult - if one desires to be
accurate. In HF, the best bench accuracy at NBS rarely rose above 1%
typical. You could get more if you had deep pockets. This begs the
question, who cares? The FCC measuring your output would use as
crummy a meter as you might find on your own shelf. Their only saving

grace is that they would have a Cal sticker on theirs (because it is required of them by law) telling them that their meter is exactly 20% inaccurate.

Source record: 179267

From Circuits and Networks by Koehler. The section on Network Analysis and Impedance Matching. Section 5-7. Conjugate Impoedance Match.

"For many applications the purpose of inserting a network between a source impedance Zo and a load impedance ZL is to effect a conjugate impedance match."

"The purpose for this is, as given in Chapter 2 section 5, is to deliver the optimum power to ZL."

"The conjugate impedance matched network, in general, is neither an image or an interative impeance match. <snip> For lossless, OR NEAR LOSSLESS, networks the magnitude of current, or of the power, may easily be determined because a conjugate match occurs at both input and output terminals of the network."

"When the generator and load impedances are resistances and the parameters of the network are lossless, the network becomes image impedance matched."

From Network Theorems Chapter 2 :

2-5 Maximum Power Transfer Theorem
"In order to deliver optimum power to a load impedance ZL that is connected to the output terminals of a network of linear and bilaterial impedances driven by an emf Es with an internal Zs, the impedance ZL must be the complex conjugate of the impedance measured across the output terminals when Es is zero and Zs is left in the circuit."

My systems are close enough to being conjugately matched to use the equations and definitions in the above chapters. Your systems may not be, but it works for me. It measures that way, it behaves that way.

It's also easy to find verification of the misuse of Thevenin and Norton's Theorems, where the theorems themselves preclude the use of an actual resistor to represent what the source looks like for anything more than describing the point of maximum power transfer.

We certainly spend a lot of time arguing about a definition that was well accepted until a few years ago in our community, and a definition that is still well accepted outside of our community.

I'd like to know where the idea comes from that Thevenin models can be used to calculate efficiency, since the rules of using the model prohibit that use. Seems like a lot of people argue using theorems they have never bothered to read.

Same here.

I can easily put up loops, but I don't.

They not only don't model to have any real advantage when installed at
the same height as a dipole, they also don't work as well as near as I
can tell from having actually "done that".

What you might do is just use a dipole, and tell people it is a loop.

I do not mean this personally so put the blow torch away! <:}

I am much more inclined to believe the prediction that EZNEC makes than
to accept what your analyzer reads under the experimental conditions you
described. Your results simply do not agree with the theoretical basis
on which that antenna is working. There are just too many things that
can take place in any experiment, no matter how well contrived and
executed, that can produce results that differ from "theory."

In itself, those results do not disprove "theory" rather they raise
doubt as to be validity of the experimental conditions.

I know that you are trying here and doing a yeomanlike job at it, but
don't be too quick to write off decades of work in this area on the
basis of a ten-minute experiment. And, as gently as I can put it, I
would not rely completely on the accuracy of that analyzer.

Please keep us posted on your work - this is interesting stuff!

Check out R & L Electronics in Hamilton Ohio. They're about 10 to 12 dollars cheaper than those listed here.

3718. conduit mast

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-28 02:28:48 UTC
From: Wayne Jones <wrjones1@home.com>
Message-ID: <A1yA5.92270$i5.3326085@news1.rdc2.on.home.com>
Source record: 179263

I want to put up a budget 30 foot 20m dipole suspended by 2 masts. One will be against my house and the other will be close to and guyed from the corner of my back fence.
I am planning on using 3 10foot sections of electrical conduit, each section smaller than the next so the sections will telescope and can be clamped with about a foot of overlap. I think the sizes I saw at Home Depot were 1 1/4, 1, and 3/4 inches diam

Does anyone know if the conduit is strong enough and how much guying is needed for a 30 foot mast?
Also how would I secure the base of the mast taking into consideration that there will be frost down to 4 feet below ground in winter.

I also saw post where someone suggested stripping electrical house wire to use for the antenna wire. I assume he meant stripping the outer casing containing the coated wires and not the insulation on the individual wires. Do you think this wire is strong enough to hang 30ft without stretching or breaking? Does anyone have any info or opinions on this?

tnx
Wayne Jones

Yeah, I guess I forgot that...If you live near Portland, OR, (actually, Cornelius) and pick it up, it just costs you $250, no shipping.

So do I :-)
I always try to match the antenna to the feedline's impedance, and if I can,
design the antenna so it has feedline (50 ohms) impedance, so I don't have to
use no stinkin' lossy matches of any kind. One in the PA is enough.
Managed to do that with Razors, 50 ohms, flat SWR and they gave me edge.
Why make RF wander back and forth in the feedline, when it should be going out?
:-) I don't mind filters and gadgets between the exciter and PA, but after the
PA and output tank, its low loss feedline all the way to antennas.

------=_NextPart_000_003B_01C028D2.46EC2C20

charset="iso-8859-1"

Thought some of you may want to try this too. Easy money maker with =
results that will keep you from spending 10-20 dollars a week on the =
lottery to return a meager 5 dollars. You're still behind no matter how =
you want to look at it!!!!

Read all of this - better chances of better returns than the lottery!!!

GET $40,000 WITH ONLY 6 BUCKS!!! THIS IS NOT A SCAM!!!

A while back, I was browsing these newsgroups, just like you are now, =
and came across an article similar to this that said you could make =
thousands of=20

CASH within weeks with only an initial investment of $6.00 plus stamps! =
So I thought, "Yeah, right, this must be a scam!" But like most of us I =
was curious and kept reading. It said that if you send $1.00 to each of =
the 6 names and addresses listed in the article, you could make =
thousands in a very short period of time. You then place your own name =
and address at the bottom of the list at #6, and post the article to at =
least 300 newsgroups. (There are about 32,000 of them out there and =
that's quite a large market pool). I invested EXACTLY $7.98 six stamps =
at 33 cents and six $1.00 bills. and boy am I glad I did!!! Within 7 =
days, I started getting CASH in the mail! I figured it would end soon =
and didn't give it another thought. But the CASH continued coming in. In =
my 1st week I made $20. By the end of the 2nd week I had a made a total =
of $1,000. In the 3rd week I had over $10,000 and it was still growing. =
This is now my 4th week and I have made a total of just over $42,000 and =
it's still coming in . Also, make sure you print a copy of this article =
NOW, so you can get the information off of it as you need it. I promise =
you that if you follow the directions exactly, that you will start =
making more CASH than you thought possible by doing something so easy! =
Suggestion: Read this entire message carefully! (print it out or =
download it.) Follow the simple directions and watch the CASH come in! =
IMPORTANT: This is not a rip-off; it is not indecent; it is not illegal; =
and it is virtually no risk - it really works!!!! If all of the =
following instructions are adhered to, you will receive extraordinary =
dividends. This program remains successful because of the honesty and =
integrity of the participants. Please continue its success by carefully =
adhering to the instructions. Here's the 4 easy steps to success: STEP =
```

1: Get 6 separate pieces of paper and write the following on each piece =
of paper "PLEASE PUT ME ON YOUR MAILING LIST." Now get 6 US $1.00 bills =
and place ONE inside EACH of the 6 pieces of paper so the bill will not =
be seen through the envelope (to prevent thievery). Place one paper in =
each of the 6 envelopes and seal them. You should now have 6 sealed =
envelopes, each with a piece of paper stating the above phrase, your =
name and address, and a $1.00 bill. What you are doing is creating a =
service. Like most people I was a little skeptical but it truly works.=20

Mail the 6 envelopes to the following addresses:

#1) WW2

9008 Mill Valley Cir.#429

Ft.Worth, TX 76120

#2) A.Koopman

2815 Rampart Circle

Clearwater, FL 33761

#3) NAR

2435 Remington Road

Green Bay, WI 54302

#4)LP

P.O Box 1641

Metairie, La 70004

#5) TMB

3354 Christie Blvd

Toledo, OH 43606

#6) K Tate

621 Smiley Road

Tonganoxie, KS 66086

STEP 2: Now take the #1 name off the list that you see above, move the =
other names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as =
number 6 on

the list.STEP 3: Change anything you need to, but try to keep this =
article as close to original as possible. Now, post your amended article =
to at least 300=20

newsgroups. (I think there are close to 32,000 groups) All you need is =
300, but remember, the more you post, the more CASH you make! Keep a =

copy of these steps for yourself and, whenever you need CASH, you can =
use it again, and again.

PLEASE REMEMBER that this program remains successful because of the =
honesty and integrity of the participants and by their carefully =
adhering to the directions.

Look at it this way. If you are a person of integrity, the program will =
continue and the CASH that so many others have received will come your=20

way. NOTE: You may want to retain every name and address sent to you, =
either on a computer or hard copy and keep the notes people send you. =
Also, it might be a good idea to wrap the $1 bill in dark paper to =
reduce the risk of mail theft.) So, as each post is downloaded and the =
directions carefully followed, six members will be reimbursed for their =
participation as a List Developer with one dollar each. Your name will =
move up the list geometrically so

that when your name reaches the #1 position you will be receiving =
thousands of CASH! What an opportunity for only $6.00 ($1.00 for each of =
the first six

people listed above) Send it now, add your own name to the list and =
you're in business! ---DIRECTIONS ----- FOR HOW TO POST TO NEWSGROUPS =
Step 1) You

do not need to re-type this entire letter to do your own posting. Simply =
put your cursor at the beginning of this letter and drag your cursor to =
the=20

bottom of this letter,and select 'copy' from the edit menu. This will =
copy the entire letter into the computer's memory. Step 2) Open a blank =
'notepad' file and place your cursor at the top of the blank page. From =
the 'edit' menu select 'paste'. This will paste a copy of the letter =
into notepad so that you can add your name to the list. Step 3) Save =
your new notepad file as a .txt file. If you want to do your postings in =
different settings, you'll always have this file to go back to.Step 4) =
Use Netscape or Internet explorer and try searching for various =
newsgroups (on-line forums, message boards, chat sites, discussions.)

Step 5) Visit these message boards and post this article as a new =
message by highlighting the text of this letter and selecting paste from =
the edit=20

menu. Fill in the Subject, this will be the header that everyone sees as =
they scroll through the list of postings in a particular group, click =
the post message button. You're done with your first one! =
Congratulations...THAT'S IT! All you have to do is jump to different =
newsgroups and post away, after you get the hang of it, it will take =
about 30 seconds for each newsgroup! **REMEMBER, THE MORE NEWSGROUPS YOU =
POST IN, THE MORE CASH YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF =
300** You will begin receiving CASH from around the world within days! =
If you wish to stay anonymous, you can invent a name to use, as long as =

the postman will deliver it. **JUST MAKE SURE ALL THE ADDRESSES ARE =
CORRECT.**=20

Now the WHY part: Out of 300 postings, say I receive only 7 replies (a =
very low example). So then I made $7.00 with my name at #6 on the =
letter. Now, each of the 7 persons who just sent me $1.00 make the =
MINIMUM 300 postings, each with my name at #5 and only 7 persons respond =
to each of the 7 original 7, that is another $49.00 for me, now those 49 =
each make 300 MINIMUM posts with my name at #4 and only 7 replies each, =
I will bring in an additional $343.00! Now, those 343 persons turn =
around and post the MINIMUM 300 with my name at #3 and only receive 7 =
replies each, I will make an additional $2401.00! OK, now here is the =
fun part, each of those 2401 persons post a MINIMUM 300 letters with my =
name at #2 and they each only receive 7 replies, that just made me =
$16,807.00!!! Those 16807 persons will all deliver this message to 300 =
newsgroups with my name at #1 and if still 7 persons per 300 Newsgroups =
react I will receive $117,649.00! With an original investment of only =
$6.00! And some stamps. AMAZING! When your name is no longer on the =
list, you just take the latest posting in the newsgroups, and send out =
another $6.00 to names on the list, putting your name at number 6 again. =
And start posting again. So can you afford $6.00 and see if it really =
works?? People have said, "what if the plan is played out and no one =
sends you the CASH? So what! What are the chances of that happening when =
there are tons of new honest users and new honest people who are joining =
the internet and newsgroups everyday and are willing to give it a try? . =
Remember, play FAIRLY and HONESTLY and this will really work. ** By the =
way, if you try to deceive people by posting the messages with your name =
in the list and not sending the CASH to the rest of the people already =
on the list, you will NOT get as much. Someone I talked to knew someone =
who did that and he only made about $150.00, and that's after seven or =
eight weeks! Then he sent the 6 $1.00 bills, people added him to their =
lists, and in 4-5 weeks he had over $10k. This is the fairest and most =
honest way I have ever seen to share the wealth of the world without =
costing anything but our time!!! You also may want to buy mailing and =
e-mail lists for future CASH. Make sure you print this article out RIGHT =
NOW! Also, try to keep a list of everyone that sends you CASH and always =
keep an eye on the newsgroups to make sure everyone is playing =
fairly.Remember, HONESTY IS THE BEST POLICY. You don't need to cheat the =
basic idea to make the CASH!! That's up to you." Better chance at this =
than the lottery!

------=_NextPart_000_003B_01C028D2.46EC2C20

charset="iso-8859-1"

Thought some of you may want =
to try this=20
too. Easy money maker with results that will keep you from spending =
10-20=20
dollars a week on the lottery to return a meager 5 dollars. You're still =
behind=20

no matter how you want to look at it!!!!

Read all of this - better chances of better returns than the =
lottery!!!

P.O Box 1641

Metairie, La 70004

#5) TMB

3354 Christie Blvd

Toledo, OH 43606

#6) K Tate

621 Smiley Road

Tonganoxie, KS 66086

STEP 2: Now take the #1 name off the list that you see above, move =
the other=20
names up (6 becomes 5, 5 becomes 4, etc...) and add YOUR Name as number =
6 on

the list.STEP 3: Change anything you need to, but try to keep this =
article as=20
close to original as possible. Now, post your amended article to at =
least 300=20

newsgroups. (I think there are close to 32,000 groups) All you need =
is 300,=20
but remember, the more you post, the more CASH you make! Keep a copy of =
these=20
steps for yourself and, whenever you need CASH, you can use it again, =
and=20
again.

PLEASE REMEMBER that this program remains successful because of the =
honesty=20
and integrity of the participants and by their carefully adhering to the =

directions.

Look at it this way. If you are a person of integrity, the program =
will=20
continue and the CASH that so many others have received will come your =

way. NOTE: You may want to retain every name and address sent to you, =
either=20
on a computer or hard copy and keep the notes people send you. Also, it =
might be=20
a good idea to wrap the $1 bill in dark paper to reduce the risk of mail =
theft.)=20
So, as each post is downloaded and the directions carefully followed, =
six=20
members will be reimbursed for their participation as a List Developer =
with one=20
dollar each. Your name will move up the list geometrically so

that when your name reaches the #1 position you will be receiving =
thousands=20
of CASH! What an opportunity for only $6.00 ($1.00 for each of the first =
six

people listed above) Send it now, add your own name to the list and =
you're in=20
business! ---DIRECTIONS ----- FOR HOW TO POST TO NEWSGROUPS Step 1) =
You

do not need to re-type this entire letter to do your own posting. =
Simply put=20
your cursor at the beginning of this letter and drag your cursor to the =

bottom of this letter,and select 'copy' from the edit menu. This will =
copy=20
the entire letter into the computer's memory. Step 2) Open a blank =
'notepad'=20
file and place your cursor at the top of the blank page. From the 'edit' =
menu=20
select 'paste'. This will paste a copy of the letter into notepad so =
that you=20
can add your name to the list. Step 3) Save your new notepad file as a =
.txt=20
file. If you want to do your postings in different settings, you'll =
always have=20
this file to go back to.Step 4) Use Netscape or Internet explorer and =
try=20
searching for various newsgroups (on-line forums, message boards, chat =
sites,=20
discussions.)

Step 5) Visit these message boards and post this article as a new =
message by=20
highlighting the text of this letter and selecting paste from the edit =

menu. Fill in the Subject, this will be the header that everyone sees =
as they=20
scroll through the list of postings in a particular group, click the =
post=20
message button. You're done with your first one! =
Congratulations...THAT'S IT!=20
All you have to do is jump to different newsgroups and post away, after =
you get=20
the hang of it, it will take about 30 seconds for each newsgroup! =
**REMEMBER,=20
THE MORE NEWSGROUPS YOU POST IN, THE MORE CASH YOU WILL MAKE!! BUT YOU =
HAVE TO=20
POST A MINIMUM OF 300** You will begin receiving CASH from around the =
world=20
within days! If you wish to stay anonymous, you can invent a name to =
use, as=20
long as the postman will deliver it. **JUST MAKE SURE ALL THE ADDRESSES =
ARE=20
CORRECT.**

Now the WHY part: Out of 300 postings, say I receive only 7 replies =
(a very=20
low example). So then I made $7.00 with my name at #6 on the letter. =
Now, each=20
of the 7 persons who just sent me $1.00 make the MINIMUM 300 postings, =
each with=20

my name at #5 and only 7 persons respond to each of the 7 original 7, =
that is=20
another $49.00 for me, now those 49 each make 300 MINIMUM posts with my =
name at=20
#4 and only 7 replies each, I will bring in an additional $343.00! Now, =
those=20
343 persons turn around and post the MINIMUM 300 with my name at #3 and =
only=20
receive 7 replies each, I will make an additional $2401.00! OK, now here =
is the=20
fun part, each of those 2401 persons post a MINIMUM 300 letters with my =
name at=20
#2 and they each only receive 7 replies, that just made me $16,807.00!!! =
Those=20
16807 persons will all deliver this message to 300 newsgroups with my =
name at #1=20
and if still 7 persons per 300 Newsgroups react I will receive =
$117,649.00! With=20
an original investment of only $6.00! And some stamps. AMAZING! When =
your name=20
is no longer on the list, you just take the latest posting in the =
newsgroups,=20
and send out another $6.00 to names on the list, putting your name at =
number 6=20
again. And start posting again. So can you afford $6.00 and see if it =
really=20
works?? People have said, "what if the plan is played out and no one =
sends you=20
the CASH? So what! What are the chances of that happening when there are =
tons of=20
new honest users and new honest people who are joining the internet and=20
newsgroups everyday and are willing to give it a try? . Remember, play =
FAIRLY=20
and HONESTLY and this will really work. ** By the way, if you try to =
deceive=20
people by posting the messages with your name in the list and not =
sending the=20
CASH to the rest of the people already on the list, you will NOT get as =
much.=20
Someone I talked to knew someone who did that and he only made about =
$150.00,=20
and that's after seven or eight weeks! Then he sent the 6 $1.00 bills, =
people=20
added him to their lists, and in 4-5 weeks he had over $10k. This is the =
fairest=20
and most honest way I have ever seen to share the wealth of the world =
without=20
costing anything but our time!!! You also may want to buy mailing and =
e-mail=20
lists for future CASH. Make sure you print this article out RIGHT NOW! =

Also, try=20
to keep a list of everyone that sends you CASH and always keep an eye on =
the=20
newsgroups to make sure everyone is playing fairly.Remember, HONESTY IS =
THE BEST=20
POLICY. You don't need to cheat the basic idea to make the CASH!! That's =
up to=20
you." Better chance at this than the=20
lottery!

Evidently this teapot tempest is all over Walt Maxwell's use of the Conjugate Matching Theorem to explain to amateur radio operators how an antenna tuner matches the transmitter to the antenna system. From my perspective, it has been a valuable description, even if not 100% totally accurate from an engineereing standpoint. Many hams have a much better understanding of their antenna systems because of Walt's writings on the subject.And it is close enough to accurate to be very much applicable.

Anyone who has tuned a PI network knows that it is a repetitive juggling act between "tune" and "load" that eventually culminates in a "tuned system" that transfers maximun power from his last RF amplifier stage to his antenna system. Change either "tune" or "load" and you alter conditions in the other, requiring that it be readjusted, repeatedly. Most realize that when "tuned up", the final adjustment is not the last word in -accurate- adjustment, it is merely the closest that his metering can show. If one utilized metering that was an order of magnitude more accurate, he could adjust for a slightly better match -but not by very much. And he STILL wouldn't be exactly matched, only an order of magnitude closer to perfect. It's like walking toward the wall, taking half the distance with each step. You never get to the wall but you soon get so close that for all practical purposes you're there. And he would have wasted considerable assets on the effort while realizing only a miniscule improvement - the law of diminishing returns in action. Evidently this PI network interaction demonstrates a part of the conjugate matching "problem" so high on the perfectionist's list of Things To Be Corrected.

What I see in this discussion is that while Walt has concentrated on teaching ham radio operators how the functional world of ham radio tuners and antennas operates by using the Conjugate Matching model, some of those persons whose function in life is to thoroughly understand and optimize all electronics to the maximum degree possible protest his use of this very effective learning tool on purely theoretical grounds.

I understand that ARRL removed his book "Reflections" from their sales inventory because of such protests by one or more of these efficiency experts. That is really a shame, indeed a travesty. "Reflections" is the one antenna book I'd keep if I could keep only one. Politics, indeed. It's past time for the efficiency mavens to realize that their argument confuses far more than it illuminates at the Amateur Radio level. As an excercise

in engineering theory it is perhaps another matter entirely, although as you well know, practical application of this concept has long been in widespread throughout the radio broadcasting industry. Maybe it's not referred to as "conjugate matching" (which seems to mean slightly different things to different people) but the concept remains.

: about the topic, have some technical merit and basis and are not character
: assinations, they belong in QEX as technical correspondence, IMHO.

: 73,
: Ed Hare, W1RFI

Ed,

If the argument is whether triodes or tetrodes make a better amplifier,
I can see good reason to hear both viewpoints since it is likely that
both people have technical merit and basis for their arguments.

My understanding is that this argument is like one person taking a 12 volt
battery and a 1000 ohm resistor and claiming the current from Ohm's law
is X. The other person says no it is Y. At that point, I expect more from
the editor than publishing both answers. Maybe that is too much to expect.

The question is what does your phrase "some technical merit and basis"
mean. That is, does an incorrect statement have some technical merit?
If the editor knows that someone is making an incorrect statement does
it really do the readers of QEX good to publish it?

I hope everyone can see that my complaint is not with the two authors,
but with what I think is poor editing.

Wayne, forget the conduit, it's not gonna hold itself, let alone the antenna. Go to the nearest scrap metal yard and you'll find plenty of 2" galvanized steel pipes for a couple of bucks. That should do the job.

Conduit is pretty flimsy. I'd rather use the fence top rail sections
they sell for chain link fences. The only problem is you can telescope.
But they are swaged at the end to be able to hook together. I have 20 ft
worth supporting a 10m vertical right now. 20 ft is real easy to put up,
but 30 ft is hard for one person. You would need a helper to help pull
it up with a guy wire, while one holds the end. But I think could be
done. Myself, if I had one 30 ft support for a 20 dipole, I wouldn't
even bother with the 2nd mast. I'd just tie the leg off to the fence
with a leader. But you'd have to go inverted v . Would work fine. If you
had 30 ft worth, and had the bottom 10 ft section clamped to the house,
I think you could get by with only one set of guys about 10 ft below the
feedpoint. The dipole would act as a bit of top guying. But actually, I
prefer push up masts. But they cost a bit more than fence rails. But
much easier to work with. Radio shack sells them as well as many TV
places. electrotex, etc. As far as the wire, I wouldn't go to the
trouble of stripping romex unless you had a load free. Lotta work. But
then again you only need 32 ft worth. I buy regular house wire at home
depot in 500 ft spools. The insulation is on the wire, which I prefer in
general. Keeps it from corroding. I use #12 or #14 gauge. #14 is plenty

strong for what you want to do. I have #12 gauge on my set of dipoles. It's so strong it will pull the mast over before the wire broke. It did that once when a teee limb fell on a ant leg. I'd use #14 gauge for yours to keep the weight down. MK

>science.

Amen, Bill. The notion that the "load line" is anything other than the transformed impedance of the *load* presented to the tube or transistor is indeed junk science. That's where I parted company with Walt and those who supported him. He, or one of this supporters, said in effect that the load line *was* the input termination of the network. But in fact it is just the transformed presentation of the load *to* the active device. That's a very different thing. His view is metaphorically similar to stating that the image formed by a lens *is* the object itself rather than a projection of it.

I also parted company with Walt when he claimed that a reflection could be generated from a superpose impedance. By definition, waves in superposition can't affect each other. They pass unaltered through any point of superposition. To say otherwise is to misuse the wave mechanics model at a fundamental level. Reflections can only occur from a physical impedance discontinuity in the medium propagating the wave. Unless that is a physical short or open, a total reflection cannot occur.

In the purely theoretical "steady state" (which would take infinite time to achieve), the sum of an infinite series of partial reflections can produce a result which may *appear* in some respects the same as a total reflection, but it isn't physically the same as a total reflection. To treat it as if it were is a conceptual error.

In perusing the Book, "Fractals Everywhere" by Michael Barnsley,
(Academic Press, 1988, ISBN 0-12-079062-9) I came across a figure that,
it appears, Chip is selling as a ground plane for one of his antennas.
It is a Sierpinski triangle, and it looks like Chip has simply copied
this onto PC board and etched the pattern.

I wonder if he realizes this is a copyrighted figure, and from a book
that pre-dates his use?

Hi Cecil,

I've installed a killfile also, but you aren't in it. Actually only
one person is, and the people who commonly only respond to him.

I now get ten posts a day, instead of a hundred.

I've never noticed that you get out of line or make childish remarks.
That certainly isn't true with the main "person" in my kill file...who
I hope will sue me someday soon as he promised.

They aren't going to stop, Ed. Just put Gilbert, and anyone else
who posts this sort of repetitive abuse, in your killfile. They
don't have anything useful to contribute to antenna discussions
anyway, so it is no great loss.

So far today I've added 12 names to my killfile for this group
because they've responded to Wacky Fracky's trolls. It sure
makes reading the group more pleasant. The only one in the
killfile I'll really miss reading is W8JI, but so many of his posts
are just baiting of Chirp that he had to go.

You could cover this entire group with a single wideband log periodic
antenna mounted on a rotator (just copy one of Radio Shack's antennas
if you want to build it, their designs are good). But for best results you'd
do better to build a log periodic for ch 2, and second one for ch 6 (necessary
on these two channels to get enough bandwidth), and yagis for ch 10 and
ch 12 (yagis are broad banded enough on these frequencies to pass the TV
channel). I'd suggest a 5 element log for ch 2, an 8 element log for ch 6, and
11 element yagis for each of ch 10 and ch 12. This will give you better gain
distribution, and the ability to point each antenna precisely at the desired
station. You can copy Channel Master single channel MATV antennas if
you want to build these.

>17 489.25
>29 561.25
>33 585.25
>35 597.25 --> important
>44 651.25 --> important
>46 663.25 --> important
>57 729.25
>62 759.25

For the UHF channels, it is hard to beat a corner reflector, though stacked
bowties would run a close second. These antennas are quite broad band
at these frequencies, so you could do it with one, though you might want to
use several in order to point them precisely at the desired stations. If you
want to build these, just copy the Radio Shack design (or for a more rugged
design, copy Channel Master's MATV corner reflector).

Note that you can't just combine these antennas, that would cause
undesireable interactions. (Each antenna will pick up *some* signal
on every channel, combining them at RF would cause destructive
interference to their patterns, ie loss of gain and possibly ghosting

problems.) You could bring each one to a single channel receiver, demodulate it, and remodulate it to a "house" cable frequency. That would prevent any destructive interference among their patterns by breaking RF coherence on the cable.

This is the way MATV systems are built, but it would require considerable "head end" equipment (you could likely find what you need cheap at a large hamfest such as Dayton). Antenna switching would be simpler, but all the sets in your house would have to watch the channel whose antenna is switched up at the moment unless you built a crossbar switcher or used a patch panel to assign a particular antenna to a particular TV set. This would be inconvenient.

> I've never noticed that you get out of line or make childish remarks.

For Gary, getting out of line and acting childish means catching
him in a mistake. Some I recall are:

There's no such thing as reflected power so it cannot cause
ghosts in a TV receiver. Reflected current cannot flow upstream
against forward current. There's no power in an energy pulse even
if the voltage and current are in phase. An energy pulse with a
vertical leading edge is possible, i.e. joules/second are infinite.
Power does not move from the power generator through the distribution
system to the load. Power cannot be measured entering and exiting a
boundary drawn around a system. If work is not done then power doesn't
exist. Remember those arguments?

But of course, scalars are easier to combine than vectors/phasors.
You just dump them in a bucket. If you know the number of seconds
in the transmission line, you can convert watts to joules and the
conservation of energy principle certainly applies. Consider a
transmission line one second long with reflections and a Z0-match.
Calculate the joules in the waves. The forward energy will equal
the generated energy plus the reflected energy. Assuming lossless
conditions, all energy generated by the generator and not radiated
or dissipated by the load is still in the transmission line.

ADVANCED POWER TECHNOLOGIES, INC.
1250-24th Street, NW, Suite 850
Washington, DC 20037

Woman Owned: N
Minority Owned: N
Number of Employees: 60

Keywords:
ULTRA-WIDEBAND ANTENNA; FRACTAL ANTENNA;
PRINTED CIRCUIT

Abstract:
This proposal addresses the problem of
creating a low profile antennaof relatively small
electrical size that can be made conformal

and integral to a variety of airborne structures and yet achieve wide band performance. As the candidate for low-profile/conformal antennas for ultra-wide band airborne sensors, APTI proposes the Printed Circuit Fractal Loop (PCFL) Antennas. The PCFL antenna has novel and other attractive features in addition to the wide band common to regular fractal antennas: 1) Constant phase center makes them a better wide band element for phased arrays or for designing circular polarized antennas for satellite communications; 2) Can be configured as a single ultra-wide band or multi-wide band antenna; 3) Easy to manufacture using printed circuit technology; 4) Readily conformal to airframe structure; 5) Lowprofile and light weight. Phase I study will focus on: 1) Numerical modeling and simple prototype validation of various designs; 2) Comparative and trade study of system and mechanical performance on differentdesigns; 3) Optimized paper design for Phase II fabrication and testing.

I thought voltages, in the form of E1 and E2 above were complex
numbers, not vectors. You can do more ordinary type arithmetic
with complex numbers than you can with vectors (division of one
vector into another is not allowed using three dimensional
vectors, also, the cross product of two vectors is not commutative.)
I was also under the impression that voltage was always a scalar
quantity, since E=-delV, where E is a vector and V is a scalar,
so I thought it was impossible to take the dot product of V and I.
Of course, you can always just multiply them using the rules that
apply to complex numbers. Is that what you have in mind? If
you guys are going to start talking about fields, vectors and
power, you might want to get a book on electromagnetics and read
through the part on the *divergence* of the Poynting Vector. I
believe you'll find it very illuminating.

It may, indeed, be a conceptual error, such as treating hydraulic fluid as a liquid when everyone knows it's just a collection of molecules. However, you may want to read the text, Field and Wave Electromagnetics, by David K. Cheng, where he reduces all the small reflections to a closed form expression using the binomial theorem -although he doesn't explicitly identify the binomial theorem as such- which gives expressions for voltage and current -sinusoidal- at any point on a transmission line. It probably won't convince you Walt is right, but it should give you food for thought.

that.
==========

It appears some people are still of the opinion that when a load equal to the design load, as described above, is connected to a generator a conjugate match occurs. This is patently untrue.

For example, a linear PA which is effectively a current source, controlled by its grid, base or gate voltage, having a very high internal resistance, has peak voltage and current ratings from which its optimum design load, a relatively low resistance, can be calculated. The two resistances are unrelated to each other.

So a conjugate match occurs extremely rarely. When it does occur it occurs merely by chance. The internal resistance does not enter into the circuit designer's load resistance calculations. He has no need to know. He usually doesn't.

It follows that calculations of the performance of amateur tuners + lines + antennas, based on the existence of a conjugate match at some point in the system, are invalid.

But don't lose any sleep about it. Without any knowledge of the internal impedance of your black transmitting box the more simple and exact calculations are available..

The theorem defines a basic principle. Ohms law is a similar basic principle, but we all use it in an approximate manner, for example 1.2452 volts divided by 3.4871 ohms is "about" 0.36 amperes.

But before we use approximations, we must realize what basic principles we are dealing with and what their limitations are.

True enough, but most amplifiers are not designed to that parameter. They are designed to operate with acceptable distortion and within the safe ratings of its components and power supply into a specific load. Distortion and not blowing up are more important than the load that permits maximum extracted power.

You have to start with a "power limited" device.
Once you have a power limited device, then you can decide whether or
not you are transferring "maximum available power" to the load - and
if you are, you will then have a conjugate match, by definition.

Hi Cecil,

Generators and alternators are normally operated at or close to a
conjugate match. Everything is done to keep them that way, and we are
in big trouble if they are not!

Generators and alternators automatically have their source impedance
adjusted to match the load impedance through the feedback loop caused
by the load sensing system that controls the field winding.

Even the energy source driving the generator winds up being controlled
to match the load by the generator, impedance limited of you will.

The power house is a good example of how maximum efficiency occurs
when an energy source and load are matched to each other.

Cecil:

I will respond later this weekend on the example but ask you think about
this for now:

100 watts + 100 watts does not "add" to become 200 watts. This would only
be true if the voltages associated with each power were 90 degrees out of
phase. If the voltages were in phase, 100 watts plus 100 watts would add to
become 400 watts. The voltages in a transmission line are complex and add
as vectors. Vtotal = V1 + V2 (adding as vectors). Ptotal = |Vtotal|^2 / Z.

Assuming Z is a pure resistance.

Get back to you on the rest later.

Steve

Reg wrote:
"So a conjugate match occurs extremely rarely. When it does occur, it occurs merely by chance."

In general, Reg Edwards is right. Someone could contrive a match by working at it.

The designer picks a safe voltage for his output devices. That peak voltage is determined by the supply he uses.

Later, the designer picks a minimum load impedance to limit the current to that which his devices will withstand.

So, as Reg says, the peak volts and amps determine the load resistance. The load for maximum rated output is is peak volts divided by peak amps.

The maximum rated power output becomes the peak volts times the peak amps divided by two.

Best regards, Richard Harrison, KB5WZI

It is much like the poser offered to mathematics students: You are standing 10 feet away from the most beautiful woman in the Universe. Every minute, you cut the distance between you by half. How long will it take you to reach her? The accurate answer is, given by people who understand the math, is that you will never reach her. The engineering student, however, may answer that after 30 minutes, you are close enough for all practical purposes. :-)

It sounds like you are saying the voltage doubles at a reflection, and
current doubles at the same time causing power to increase by four.

Can you explain in detail how that would happen?

Since power is a scalar, of course it does. Power is a scalar
measured at a point past which energy flows.

> This would only
> be true if the voltages associated with each power were 90 degrees out of
> phase. If the voltages were in phase, 100 watts plus 100 watts would add to
> become 400 watts.

Nope, you forgot current. If the voltages are in phase, the currents will
be out of phase, keeping the 100+100=200 math consistentent. At a Z0-match,
the ratio of V/I must change because the Z0 of the transmission line
changes. Thus, when transistioning from Z0=50 to Z0=300, the voltage will
indeed increase but an exactly corresponding decrease in current will occur
which keeps energy conserved. Remember, reflected power has the voltage and
current 180 degrees OUT of phase. If the voltages add, the currents will
subtract (and vice versa).

Methinks he forgot that reflected voltage is 180 degrees out of phase
with reflected current so if the voltage phasors add positively, the
current phasors will add negatively, i.e. subtract. Thus, the power
obeys the equation (N*V)*(I/N), i.e. for a constant amount of power,
if voltage is doubled, current is halved. Otherwise, the conservation
of energy principle would be violated.

Doesn't this put a lot of rf in the car?

Yes, and I'd be there in three minutes, because, after three minutes,
she'd be close enough to make me say to hell with the damn problem.
Why would an engineering student wait so long? The series converges
very quickly.

I disagree.

> Generators and alternators automatically have their source impedance
> adjusted to match the load impedance through the feedback loop caused
> by the load sensing system that controls the field winding.

The output impedance of a generator, defined as the rate of change of output voltage with respect to a change in output current, is determined entirely by the output voltage regulator feedback loop characteristics. In most simple systems like automotive alternator/regulator systems and small power plants, the loop gain, and therefore output impedance, is essentially constant over most of the operating range. A slightly better approximation is that the loop gain decreases, and therefore output impedance increases, as the output current rises and the field begins to saturate.

Usually where there is only a single generator involved and the transmission network is small, the voltage regulation loop gain is set as high as possible while insuring unconditional stability for all likely load characteristics and throttle settings. The result is the lowest possible output impedance (greatest stiffness) consistent with overall stability. This condition has nothing to do with a conjugate match.

In some systems such as small construction power plants powered by an integral internal combustion engine, the voltage regulation is sometimes compromised to reduce the likelihood a temporary overload (surge) will stall the prime mover.

More complex systems involving multiple generators interconnected through a transmission and distribution system having significant impedance (inductance) require a more sophisticated approach towards insuring system stability. In some cases, the voltage regulation loop of (some) of the individual generators is, for practical purposes, opened, and either power or current becomes the regulated variable.

> The power house is a good example of how maximum efficiency occurs
> when an energy source and load are matched to each other.

Ideally, large scale power generation systems are designed for the lowest possible operating cost over the life of the system. Sometimes

cost minimization is not optimal due to shortages of capitol or economic uncertainties having to do with the long term value of money. For various reasons, most of them obvious, a cost optimized power plant will consist of a generator and prime mover which peak in efficiency when operating at a power level somewhere between average and peak output power. As far as I know, this outcome has nothing to do with conjugate matching of the power plant to the load.

Hi OM,

This seems a good opportunity to introduce the group to another form
of security - no not the encryption employed above (stumps the prof,
but most kids pick it up the second day they're on the net) but of a
new service on the internet.

That service comes to us courtesy of:
Anonymizer.com
Rewebber.de
Freedom.net

These sites offer the world a new way to secure a document to be
posted to the internet anonymously (if you choose).

So what? you might ask. But wait, there's more!

This document cannot be tampered with, it cannot be removed by any
agency, and it cannot be traced to you (if you so choose). In fact,
the server holding the document is wholly unaware that it is in
possession of it. Administrators cannot find it in their system, this
is impossible. You can destroy the server it resides in, and another
copy somewhere else will replace it automatically.

One may say that it is impossible to chip this security.

>Best regards, Richard Harrison, KB5WZI

Nothing magical at all about a resistance that is non-dissipative Richard.

For example, if you remove the feedback from an alternator and fix the field excitation at a given value, and change the load, it behaves EXACTLY like the source is a "resistance limited" source except the dissipation involved is very very low (in a good alternator design).

No matter what the load, when feedback is restored, the alternator adjusts itself to supply the required amount of energy and no more....and does it without unwanted dissipative resistance. If you remove the feedback and fix the field at that flux level, a load pull will reveal the alternator is operating at the point where it's source resistance looks awful close to the load resistance.

Of course you could put a resistor in series with the output and do the same thing, but that wouldn't be smart.

Thank goodness we have non-dissipative parts of impedance, or we'd have some real power control problems that could only be solved by wasting a lot of energy!

Gee, no SW receivers or transmitters huh? How did people justify their AM/FM radios, TVs, cordless phones, cell phones, wireless alarms, etc.?

I have lived in such situations and my policy has always been "what the neighbors don't know won't hurt them". I just ignore all the CC&R crap and do my own thing. Think "STEALTH". I found it to be great sport fooling the neighbors and condo asses (ooopps, I mean condo associations). Remember, those rules are written by people who, in general, tend to be from the lowest inellectual quartile and know virtually nothing about transmitters, receivers, antennas, "short" waves, "long" waves, frequency, etc., etc. In short, they're STUPID and can be fooled quite easily.

The house we now own has similar CC&Rs and I have a wire antenna farm plus a six meter beam on our property and I can run up to 1KW output. None of the neighbors even has a clue!

Like the Nike slogan says: "Just Do It".

Tom, W8JI wrote:
"Generators and alternators are normally at or close to conjugate match."

I don`t think so. In power grids, machines close to the loads are combined to provide enough power to cope with the load and contingencies.

Nearly full loading of generators is more efficient than light loading, so machines are added and subtracted so that most are nearly fully loaded at nearly all times.

Maximum loading is set by temperature rise in the machine and has little to do with load matching.

Best regards, Richard Harrison, KB5WZI

3793. Arrangement of Cliffdweller slinky dipole

Newsgroup: rec.radio.amateur.antenna

This is the antenna I am using:
http://www.usa2way.homestead.com/CliffDweller.html

Which indoor setup would provide better performance?
1. Mounting the entire length of the antenna along the side of the room containing the windows. This keeps the entire antenna near the outside of the apartment but limits its length.
2. Mounting half the antenna along the side of the room containing the windows and mounting the other half on the adjacent perpendicular wall. This gives me a longer antenna, but half of the antenna does NOT face the outside.

In addition, ideas on how to disguise this antenna (artwork?) if I use it as a temporary outdoor installation are welcome. Please note that I live in a ground floor apartment with no trees or bushes for concealing things. Now I wish Martha Stewart were a ham.

> Does the fact that ARRL still makes the articles available change your mind about the conspiracy theory, Dick?<

It's not called a conspiracy, it's called editorial blacklisting. Past QST articles can't be "archived out" and made to vanish--that's an invalid argument.
A book may, on the other hand, be pulled from publication at any time for more than one reason. If it doesn't sell, it may not be worth reprinting and dropped. Or, if a senior technical editor opposes it's theoretical approach, it may be dropped and replaced with something more to his liking. Many in the industry believe Reflections was taken off the publication list because of the latter -- "reflecting" one of the risks ham radio faces when one publisher enjoys a near-monopoly in the dissemination of technical information.

I, for one, would like to purchase a new a copy of "Reflections" because I loaned mine to someone a while ago and never got it back! People "own" books precisely so they don't have to dig through a mountain of articles to get the information.

There's conduit, and there's conduit... If you used PVC conduit, it would be like a wet noodle unless you added LOTS of guys. If you use EMT conduit (the thinwall stuff meant to be bent) it likely would fold with not much more than the antenna tensioning. But it might work to put in rigid conduit, which is extremely similar to steel water pipe, but guaranteed to have a smooth enough interior to not abrade the wires installed in it. On the other hand, you may find that galvanized water pipe is cheaper. I'd recommend getting a full 21 foot length of perhaps 1-1/2" schedule 40 (and maybe even schedule 80) for the lower section, as a minimum...if you have a way of carrying 21 foot pieces. Disclaimer: no matter how you do the job, it's YOUR responsibility to insure that the installation is safe electrically and structrually.

Cheers,
Tom

"Dissipation" is often a bad word implying something we don`t want.

Dissipation can be a synonym for dispersion. A wire can radiate both radio and heat. Thus it is dissipative in some sense for both.

Do you have access to your attic? In a similar situation, I drilled a
1/2" hole thru the roof above the attic access hatch, allowing me to
raise and lower a 20-foot vertical. Wasn't the best antenna in the world
but worked well with a tuner. Our CC&Rs forbid "attaching" any antenna
to the property. This one wasn't "attached".

Hi Bart,

You and Tom are arguing the same side of the case, but you have a feedback loop that does not include the load, simply the output.

As you state, the feedback loop is the principal mechanism for stabilizing an amplifier's characteristics. This was established at Bell Labs in 1938 by a series of lectures from Hendrich Wade Bode. His lectures became central to all system's design that followed, such that we find the Bode plot a commonplace engineering representation for an amplifier.

Negative feedback (or error, or noise gain in Bode's work) is directly causal AND correlatable to output resistance, input resistance, distortion, Power supply rejection, and other exotic variables. The factor relates very simply. The lesson learned is the more feedback, the better the amplifier's ability to accurately transform the signal's power level.

It is commonplace in amplifier design (and I am speaking of them generally, not the Henry) to enlarge the feedback loop by including the load (as separate and distinct from the input/output connectors). The typical Ham has very limited opportunities to observe such examples, but one that may be found is in the laboratory power supply (mine from Acopian is an example, HP makes them too); even the small open frame linear supplies offer this (but again, not commonly available except at swap meets where military/industrial surplus is found).

These supplies have four output leads. Two supply the current set at a voltage that is close to the user's selected value. The other two leads go to the load (yes so do the current leads) to complete the feedback loop as the "sense" leads. These leads provide the error signal back to the closed loop amplifier responsible for setting the voltage and current conditions. In fact these leads are the principal

part of that loop everyone speaks of.

When ANY Power Supply applies current to the load, there is some voltage droop between the output connector of the supply and the input connector of the Load. The "sense" leads conduct no appreciable amount of current and thus do not suffer the same droop. When that voltage across the Load is passed back to the amplifier, the difference between this voltage and the voltage at the output is translated into a voltage boost at the output such that the Load sees the voltage set by the user (a specific example is below).

This technique was invented by Lord Kelvin and in Metrology there is a class of connector that looks like alligator clips (a pair of them) that is actually this same four lead configuration. These are call Kelvin clips and they are used for high precision power sources and are applied to precision measurements of resistance. By moving the loop outside of the amplifier (power supply as illustrated here), the amplifier can be adjusted to compensate for the load variation - this is what Tom is talking about.

The typical case is a 13.6V common two lead Power Supply supplying 25 Amps through 0.1 Ohm lead resistance which causes a droop of 2.5V presenting the load with 11.1V @ 25A. The four terminal Power Supply would instead source 16.1V @ 25A at the output connector and MAINTAIN 13.6V @ 25A at the Load connector. If the Load were to drop such that only 2.5A were required at 13.6V, then the four lead Power Supply would sense the change in the droop and lower the voltage boost such that the load would still be MAINTAINed at 13.6V @ 2.5A with the supply now sourcing 13.85V @ 2.5A. The two lead power supply will source the same 13.6V @ 2.5A, and the Load only suffers slightly with 13.35V @ 2.5A.

It will be noted that the two types of Power Supply above display considerably different efficiencies or states of match - depending on where the lead loss is included. The two lead Power Supply example is artificial in that variation in current demand will cause some variation in voltage at the output that I've neglected to treat for simplicity's sake.

With the loop extended outside of the amplifier (power supply in this example), this loop thus embraces additional loss within it and draws it into the Source Z. This one fact alone is the principal source of considerable confusion when the topic of Source Z arises in this group. This is why Metrologists speak of planes of the load, planes of the source, planes of measurement and so on.

This also illustrates the failure of metaphors. The topic diverged into issues of the power grid, and the power grid does balance and achieve conjugation, but in a way that is alien to the RF Amplifier topic. My example of 4 lead power supplies is equal in alien content, but it brings accessibility to the discussion.

For all intents and purposes there are two feedback loops in the common RF Amplifier (both barefoot and for the Henry). The first one is found in the coupling capacitor feeding the output back to the input (not to be confused with the equalization circuit). This controls/reduces distortion and stabilizes input/output Z. The second is found in the SWR circuitry that as fed back to the exciter, which in turn controls (through a PIN diode acting as a voltage variable potentiometer) the amount of Power that can be sourced (and is typically called "fold-back"). All may note that BOTH loops are internal, and they should all note that even so, these loops by definition encompass all losses to combine the circuitry into a monolithic Source. Thevenin would understand.

Hi everyone!

I want to make my own antenna (i surely can buy one in radio shack but i want to make something with my hands). That antenna have to capture the following freqs:

Channel Freq
02 55.25 --> important
06 83.25 --> important
10 193.25 --> important
12 205.25 --> important
17 489.25
29 561.25
33 585.25
35 597.25 --> important
44 651.25 --> important
46 663.25 --> important
57 729.25
62 759.25

What kind of antenna i have to use? (i think that i have to use Yagi AND Log Periodic, am i right)?
Some URLs with designs?
Maybe someone have constructed something similar?
Please HELP

3804. Inverted V

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-29 00:00:00 UTC
From: Wayne Jones <wrjones1@home.com>
Message-ID: <7Y6B5.95490$i5.3436338@news1.rdc2.on.home.com>
Source record: 179030

Well, thanks to this newsgroup, I have been able to settle on the best antenna for my 20m cw qrp operation.

I plan to put up a 30 foot mast made of fence top rail. The mast will extend about 14 feet above the edge of my 2 story house.
With the antenna attached to the ends of the roof I get an inverted V with legs of 21 feet and an angle of 90 degrees.
With the active part of the leg at about 16 feet on each side, the remaining wire will elevate the antenna about 3 feet above the rain gutter that runs along the edge of the roof under the antenna and should keep the ends out of the snow in winter. I will use a plastic plumbing pipe T to insulate the top of the metal mast from the antenna wire.

I understand that with an inverted v, the legs have to be slightly longer than a horizontal dipole. Is it possible to come up with a good guess as to what the length should be?

Also, will the impedance be around 50 ohms at the center? I understand that the impedance varies with the angle of the V.

Tnx
Wayne Jones

I think we'd be in big trouble if generators *were* matched to their load.
Maximum power transfer is not desired. Supplying the connected demand, no
more and no less, with maximum efficiency is the aim.

The generator's impedance (especially the real part) is made as low as
possible. To raise it to equal the load resistance would be destructive.

Hi there Cecil,
There are 2 voltage waves and 2 current waves at the point of interest.
Let's say that the phases are all identical to keep things simple. If
the voltage waves combine and the current waves combine, does
(E1+E2)*(I1+I2) equal E1*I1 + E2*I2 ?

I think it means you will have to wear a suit and tie 24 hours a day.

I also think the author of that sentence should be in a white suit with
wrap around sleeves.

As I recall, the resonant frequency goes down and the impedance goes down
as you swing the legs away from horizontal. Mine wound up at 48 Ohms.

Why don't you download the demo copy of eznec and play with it? The demo
version will do a dipole.

A 1/4 wave mobile whip (or fixed ground plane) cut for--say 150 or 151 MHz will cover both the 2 meter and business bands with less than 2:1 VSWR. Once you get into 5/8 wave or half-waves in phase, forget it. They are too narrow.

Thanks for hanging in there and replying, and for posting the graph - great!

Something surely is going on. Both you and Roy have replied, and if I understand
you both correctly, your real world experience has closely matched the EZNEC
modeling. Meanwhile, I've always gotten low swr pruning dipoles. This is going

to drive me crazy. Roy mentioned coax - maybe its the coax I'm using. I used the
same 20' piece of rg58 coax for all the 6M dipoles I built in response to this thread.
(I made each reading with that 20' and also re-measured with an added short coax

jumper) I guess I'll have to make a 1/2 wave piece of coax out of some 8X and re-do
the measurements. I'll also "test" the analyzer against resistors - that may be a valid
test, but says nothing about how well it does in the presence of reactance. Next,
I'll bring the makings of a dipole to a friends house, put it together and prune it for
minimum swr at 8 feet on 6 using the analyzer. Then I'll ask him to measure it with
his return loss bridge and see what he gets.

After that, if I end up close to 1:6 to 1 minimum swr, I'll be satisfied. If not,
I don't know what to do next. Any ideas?

The demo version of EZNEC 3.0 is free and available from
http://eznec.com. The "Test Drive" tutorial exercise takes you through
the design of first a dipole, then an inverted vee. So by the time
you're finished with it, you'll have a model that you can use to answer
your questions. To get to the Test Drive in EZNEC 3.0 (either the demo
or full version), click the Help menu, then select Contents, then Test
Drive.

3821. Re: conduit mast

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-29 00:00:00 UTC
From: Mary Anne Olsen <wolsen@erols.com>
Message-ID: <39D513E7.DA5FB9B6@erols.com>
Source record: 179047

I put up a masts (flag poles) using 2 inch EMT. Each flag pole has 5 sections; 2 for the base and 3 for the mast for a total of 30 feet. Criteria was that it was to be temporary until a Butternut was installed and I didn't care if it came crashing down as long as no harm would be done. No guys were used and this was done two years ago. The dipole had a total length of 104 feet using the standard 7 strands of copper wire. I have sandy soil and used a shop vac to dig a five foot holes. Freeze line is probably a foot at most. Top of one mast is about 6 feet off vertical and the other about 3 feet. This bowing is due to not aligning the sections together properly. Had a little iced storm last winter and the wire stretched an extra 10 feet but it's still standing. It requires two persons to raise or lower. Bill N3TVU

What I would personally find very interesting is a plot of the resistive part of the reactance vs height above ground. I would like to compare the way it varies against the graph I posted at http://www.arrl.org/~ehare/temp/6mdip.jpg . That graph assumes that the physical surface of the earth is the ground that is modeled. I have often wondered just how far below the surface the "real" ground is. :-) A simple measurement, but I lack the necessary test resources -- the round tuit. :-) If you get some results of R vs height, I can add them to the graph and then we can REALLY have something to talk about. :-)

IMHO, the measurement of the height above ground at which the resistance is the highest would be a very good way to estimate the actual depth of the ground.

As an aside to the data, what is the present state of your earth? Wet? Dry? Do you have an estimate of the characteristics of your soil? Unfortunately, I didn't see a tremendous difference in R vs ground characteristics. With "very good" ground, the R at 6.2 feet above ground was 90.23 ohms. With very poor ground, it was 82.29 ohms. Although I would like to think that one could first determine the height of maximum R (in this case, with VG ground, it was 6.2 feet) and then use the actual R value to obtain an estimate of ground characteristics, I fear that 82 vs 90 ohms is not a tremendous swing and that the actual R value would vary a bit from what EZNEC predicts due to other local variables. But if someone IS over "very poor" ground (ie, dry desert?), and could do the measurement, then improve the ground with moisture and salts, then do another measurement, it sure would be interesting to see how close it comes to what EZNEC predicts. The thing to watch out for, especially when the ground is improved, is if the effective height of the antenna above ground varies as the "ground" moves from the surface to lower depths.

Roy or others, have you heard of or done any work on the actual depth of ground relative to the surface of the earth? I am just musing here, hoping to ferret out some explanation for the differences between modeling and ehsjr's measurements.

I'm not sure what you mean by the "actual depth of the ground". Do you mean, what is the depth (or distance below an antenna) you could place a perfect ground to produce the same pattern and/or impedance as you'd get over real ground?

If that's what you're asking, the answer is that there isn't any such depth. Or are you asking something else?

Proposal Title: High Performance Miniature Antennas for Hand-Held Personal
Communication Systems (PCS)

Principal Investigator Name: Nathan Cohen
Principal Investigator Phone: 617-489-6952

Firm

FRACTAL ANTENNA SYSTEMS, INC.
Suite 1218 5100 North Ocean Blvd.
Fort Lauderdale, FL 33308

Woman Owned: N
Minority Owned: N
Number of Employees: 4

Keywords: MINIATURE ANTENNA FRACTAL ANTENNA
Abstract: We propose to develop miniature antennae built on fractal designs.
The antennae will be built to exhibit the recently discovered advantages of
fractal antennae--shrunken size; broad/multibandedness; reasonable radiation
resistance. These fractal antenna will be designed to accomodate a number of
constricted form factors including: covert or embedded mounting; top mounting;

and multiple mounting. The antennae willbe tested for performance at a variety of frequencies allowing for prototype production for satellite links,cell point to point, and so on. These prototypes will also be directly applicable to commercial use in wireless, cellular,and other consumer telecommunications useages. Miniature embedded fractal antenna of broad bandwidth have the potential to replace most extant commercial designs in hand-held configurations, without breakage and with higher efficiency.

Just getting my money's worth out of the IEEE dictionary, Richard. :-)
"dissipation - loss of electric energy as heat" It's not always
undesirable. It's how I heat my house in the winter.

Hi Cecil,

Look up heat in your dictionary, does it qualify as radiation? Or do
they have two part definitions for that too?

Mine is heated by chemical conversion -- wood into BTUs.

I supplement the heat in my bathroom with a small heater -- the only device
I know of that is 100% efficient. :-)

My personal solution was to killfile Chip a long time ago. He was only the
second person ever from this group to wind up in the killfile (the other was
the equally childish Cecil Moore). But that wasn't sufficient since some
posters insist on following up on his trolls. Their responses were so
congesting the group that I could no longer spend the time to follow it.
So now I'm reluctantly killfiling those who persist in posting follow ups
to his trolls. That is beginning to whittle down the volume of the group
so that I can follow it again.

I'd suggest that anyone who really wants to deal with this problem should
do the same. Killfile Chip and all who respond to his trolls, particularly those
who respond with canned statements or insults. If people begin to realize that
by responding to Chip they wind up in the killfiles of many of the readers of the
group, they may stop responding to him. Those who persist in responding, we
probably don't want to read anyway because they will have shown themselves
to be too boorish to be worth the time to read.

Get a big attic and string up a few dipoles. More bandwidth. Better signal. Wire is cheap.

An what you save over a loopie antenna will buy you a fine Bird watt meter to help you tune them pesky dipoles!

Bob
k5qwg

p.s. spend $34 and subscribe to QST -- then go to the arrl web site and look at the members-only reviews on all those expensive loop antennas. take their word at qst, not mine...

Not really, I am essentially asking if the surface of the earth is where I should presume the ground I model to be. In my part of the world, the first several inches of soil can be quite dry; would I presume correctly that the antenna will perform as if it were located a bit higher than it really is above the physical surface of the earth under those circumstances?

Hope I am not explaining this too badly. :-)

kilowatt out, or something similar?

I don't think so.

>The generator's impedance (especially the real part) is made as low as
>possible. To raise it to equal the load resistance would be destructive.
>
>73--Nick, WA5BDU

The generator's "real part" is raised as the load resistance decreases
(higher resistance load) and decreased as the load resistance
decreases. The dissipative part of the generator's impedance is made
as small as possible within cost limitations.

The feedback loop that sense load current backs-off the generator's
field excitation, which has the effect of raising the non-dissipative
"resistance" of the generator.

If it didn't, the system would have terrible efficiency at middle load
ranges.

Remove the feedback, and adjust the generator's field for proper
operation at a given load, and you'll find in a well designed
generator it acts just like the generator is sourcing through a
resistance close to the load resistance in value...with very little of
that resistance making heat.

> (E1+E2)*(I1+I2) equal E1*I1 + E2*I2 ?

Actually, there are three voltage and current waves forming an
interference pattern at a Z0-match. Neglecting losses, there's
the voltage/current generated waves, the voltage/current reflected
waves, and the voltage/current forward waves. At a Z0-match point,
everything is either in phase or 180 degrees out of phase. At a
50 ohm coax to 300 ohm twinlead junction, we know the ratio Vg/Ig
equals 50 ohms, the ratio V-/I- equals 300 ohms, and the ratio V+/I+
equals 300 ohms. If we assume Pg to be 100 watts and that there is
an SWR of 5.83:1 on the 300 ohm line, then P- equals 100 watts and
P+ equals 200 watts. This gives us all we need to know. Given a
reference of Vg = 71v@zero, Ig = 1.4a@zero, V+ = 245v@zero,
I+ = 0.82a@zero, it's obvious that V- = 173v@180 deg and
I- = 0.58a@zero. The voltage just to the left and right of the
Z0-match is 71v@zero = 245v@zero + 173v@180 and the current just
to the left and right of the Z0-match is
1.4a@zero = 0.82a@zero + 0.58a@zero

These values are all rounded so the equations are not exact
equalities. All phasors are at zero degrees except V- which,
as predicted by theory, is 180 degrees out of phase with I-

Programs like EZNEC assume that the ground is homogeneous. If the real ground isn't (which I'm quite sure is usually the case), there's probably not a single height at which you can place the homogeneous ground model which will imitate the real ground in every way. I've also questioned whether there are single values of conductivity and dielectric constant which will reasonably imitate a stratified ground, but don't know the answer.

LOL! Who the hell am I to flame anybody for something
technical about antennas! Besides, try as I might, I can't find
anything in your post to flame.

> I am much more inclined to believe the prediction that EZNEC makes than
> to accept what your analyzer reads under the experimental conditions you
> described.

Me too. That's why I am so puzzled. I've NEVER had a dipole whose
minimum swr after pruning was 1:8 to 1. That's why I asked others to
experiment and post their results. And why I asked Ed to check it out,
to ensure that there wasn't a "finger check" when he ran the program.

A possible answer came in E-mail. It said: "Note that minimum SWR
is not always consistent with resonance." And Ed's post talked about
1:8 to 1 at resonance - it didn't say minimum swr.

Ok that said, I went further. I attempted to build a stiff wire antenna
to avoid the effects of end loops/insulators. This was a half-assed
antenna. I made it out of #6 bare copper wire. I had to use a 26"
piece of 1/2 plywood in the center - I mounted the elements to that.
It worked temporarily, but the elements would slowly sag. Anyway,
I screwed the wood to the top of an 8' 2x4 and the swr was flat (could
just barely see the needle move on the swr meter) at the design frequency.
But when I moved the thing close to the house, the swr went up to about
1:7 to 1. Unfortunately, I couldn't move the thing around as I hoped without
causing the elements to sag before the motion was complete, so I can't
say that changes were solely due to proximity to the house. Sigh. I guess
I'm going to have to get fiberglass poles to simulate sideband's antenna.

I then disassembled a 3 element 6 meter yagi that I've been experimenting
with. (Trying to learn stuff you guys already know.) I kept the driven element
on the boom. Swr was flat after adjusting the gamma. This is a monopole,
so it doesn't count - but I still get a flat swr. I put together a shortened
copper pipe (1/2 inch) dipole fed thru a 5 turn coil wrapped on a broom handle
and I can adjust that flat, too, by compressing/expanding the coils.

Bottom line - I can get the swr below 1:2 to 1 on all of these antennas.
Sideband's dipole gets a minimum of 1:8 to 1 and goes up on either
side of that (or it did, before he moved the coax). So I still maintain
that there is (or at least was) something wrong when the minimum
swr was 1:8 to 1, and I challenge Ed's assertion that the antenna
is working perfectly. Maybe it should be 1:8 to 1 at resonance -

but I can't see it being 1:8 to 1 minimum in the absence of effects
other than being 8' above ground. I believed then, and still believe
that it is the effects of being near the structure that are causing
the minimum Swr to be 1:8 to 1 (originally) and 1:4 to 1 (now).
I believe that the antenna should be able to be adjusted so that
the minimum swr will be below 1:2 to 1 if it is installed 8' above the
ground in the clear.

Does EZNEC insist that a 50 mhz dipole (8' above ground but
otherwise clear of influence of nearby objects) at *minimum* swr
will be close to 1:8 to 1 ? If so, it is wrong.

Another question: I've always thought that a dipole exhibited minimum
swr close to resonance - again, assuming it is in the clear of objects
other than ground.

Isn't NBS now NIST, and the standard meter, not a platinum
meter stick but 1,659,763.73 vacuum wavelengths of light resulting
from unperturbed atomic energy level transition 2p10 ï¿½ 5d5 of the
krypton isotope having an atomic weight of 86 (= 1m/1,650,763.73 =
0.605,780,211 ï¿½m)?

I was interested in a fractal antenna for 440 Mhz, and in the theory
behind the idea of possible benefits of the type, but the person I
though might have the answers was as coy as Sally Rand in her
fan-dance routine.

Hmmm...where did you see the term used? If I used it, I suspect it would be in context.

An ARRAY can provide power pattern agility through the changing of the spatial frequency spectrum and weighting. Fractals have some very useful attributes in this regard, but that is beyond the general scope of interest of this NG.

The evidence is compelling and over almost 25 years old.

Random fractals, for example, have long been shown to be optimized antenna.
That includes optimized compared to other loading schemes.

Recent examples of random fractals, called 'genetic antennas' also follow said
optimzation.

A good place to start is:

OPTIMIZATION OF WIRE ANTENNAS by Landstorfer and Sacher, Wiley Interscience,
1985.

The data on deterministic fractals is also compelling. This includes recent and
as yet unpublished work done on DoD and commercial contracts.

This work will appear next year.

>I was prepared to believe the claims at one point (what do I know, my
>training is in biology). Now I am convinced that you are right.
>

Ignorance is its own reward. If you consider that one is allowed to ignore
publications such as Electroics Letters; Fractals, IEEE Transactions; and many
others, then I imagine that it is possible to believe that one should have an
OPINION on said matters.

The minute that science becomes an enterprise where one must put OPINION above
fact is the minute I leave it.

Haven't seen an exit door yet, nor a reason to look for it.

Incidentally, I am astounded that a so-called antenna person doesn't even know what a fractal is...and calls his so-called novel designs 'random.'

When someone speaks of directive gain, they mean directivity. Ie. An antenna does not provide gain as in power amplification (total radiated power can never be greater than delivered power) but rather gain as a function of directing energy, hence directive gain aka directivity.

Both statement 1 and statement 2 above say exactly the same thing. Both are correct.

Excuse me; it is not available to "anyone to check". It is available to members of the fractal antenna reflector only, at their request, and with certain reasonable conditions. This file, and any derivatives in which said antenna design is easily recognized, is copyrighted material to Fractal Antenna Systems, Inc.

Any unauthorized publication and distribution constitutes copyright infringement under U.S. copyright law.

If you are aware of any infringers as described above, please notify me ,and Fractal Antenna Systems, Inc. will notify the infringer and request that they remove said file from publication and distribution, under penalty of suit.

Thank you for your assistance.

Nathan Cohen, Ph.D.

>Anyone can check this out...the TRUTH.
>
>http://www.qsl.net/kb7qhc/antenna/fractal/n1ir/k2/index.htm
>

The truth is that Mr. Clarke has posted unauthorized copyrighted file and images which thus constitute copyright infringement. Mr. Clarke was sent a request on August 14 to remove said material.

If he does not do so, as the letter so stated, by 15 October, 2000, he will be liable for any and all costs, including attorney fees, incurred in the ppotection of said copyright material held by Fractal Antenna Systems, Inc. The K2 Fractal Flyer file and images have been so identified.

Now, Mr. O'Neal:

Could you kindly tell us how it is possible that Mr. Clarke--that is the "TRUTH"--can possibly compare the IMPEDANCE of this K2 Fractal Flyer antenna over real and perfect grounds, and come to the conclusion that it has 15 ohms of ground losses??

If we compare, for example, the 'H' antenna with the K2 (and note that the K2 has higher field strength at low angles BTW) , we see that there is fairly little change in feed impedance for the H when it is placed over perfect ground and real ground. Are we to conclude--based on Mr. Clarke's logic--that the 'H' antenna thus has BUILT IN ground losses--even over perfect ground?

Or shall we conclude that Mr. Clarke does not understand the implementation (oin this case)of ohm's law; wishes to infer ground loss resistance by a comparison where the power pattern and current max position changes, and so on?

This is a fairly typical example of the incorrect info that Mr. Clarke has provided on this site--independent of copyright infringement. It is a pity that readers are misled by this.

Curious to know your comments on this.

The Zo match point is where multiple rearward traveling waves combine such that the total rearward traveling wave is zero (wave cancellation) , hence the steady state match.

The only energy "joining" the forward traveling wave is the energy that is partially re-reflected at the point of reflection, which, in the case of the tuner, is not at the match point.

I told Walt that I would not debate these particular points on usenet again. Would you prefer to take this topic offline?

I don't do conspiracy theories, Ed, but when the volume of rumors and commentary was way too extensive to be ignored and the question marks began toappear. Meanwhile Walt's book and other material disappeared from League pubs and sales lists...And the book contains considerably more expanded material than the QST articles - I have all those QST issues. As I recall Walt stated in the book the he was never able to finish the QST series thus they are incomplete..

So it appears the Conjugate Match Theorem is useless in describing any real-world network, since there exists no such thing as a completely lossless four terminal network that I am aware of. It is not to be used outside the realm of theory. Otherwise it's only useful application would seem to be exactly as Walt Maxwell has utilized it - to approximate what happens.

Is the HF Loop antenna from MFJ - MFJ-1786 - a 'good' antenna? I am considering a house in a restricted area, so a loop in the attic might be an option. Any suggestions will be greatly appreciated.

73,
Fernie/KE4MAI

3867. Help with 8 element Yagi design for beginner.....

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-29 04:02:19 UTC
From: alex <A_L_E_X1@yahoo.com>
Message-ID: <970200042.203229@nomad.vif.com>
Source record: 178978

Hi, everyone!

1. Who can tell me where to find a step-by-step guide about 8 element Yagi design?
I want to construct it by myself, but i don't know much about radio freqs and other related stuff.
Please Help!!!

2. Is there somebody from Montreal, Quebec, Canada? I want to know if a Yagi antenne will help me with capturing channels: 2, 6, 10, 12, 17, 31, 33, 35, 44, 46, 53, 62. The important ones are: 2, 6, 10, 12, 33, 35, 44, 46.
Is it possible to capture all of those with one antenna and will i see it fine or not? Maybe you had the same situation?

Thanks

A_L_E_X1@YAHOO.COM

p.s. you can reply on this group or you can send me an e-mail.

Dear Group:
That is about what a group of our faculty who teach circuits decided. It is interesting, but practical uses are few. Little, if any, time is spent on the theorem any more. It might be mentioned as an example of intellectual excess as it was misused (some time before I was born) to prove that electrical power plants could not be built - half the power generated would be dissipated in the power house resulting in melted power houses. [I understand the error of this as well as you do!]
Cases exist where matching to reduce reflections is important.
The most embarrassing moment of my life occurred when, as a grad student of John Kraus, I blurted out in the middle of one of his wonderful lectures that he was wrong to optimize the front end of low noise receivers by conjugate matching their inputs. I muttered something about "well, that was close, but there were other considerations." I shot out of the class (when it was over) to my apartment (almost across the street) and wrote him a paper where I proved that for best s/n ratio the front end needed to be slightly mismatched. Ran back to his office and slipped the paper under his door. We never exchanged a word about the incident and, so I heard, the lecture was changed. He is a great man and a great teacher, but the darn theorem causes things like this to occur - it is too alluring. As the old phrase has it, in handgranades and matching, close is good enough. ....and it is now so late that all theorems are true and all women are beautiful.....

3873. Re: new antenna help (using MFJ analyzer)

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-29 23:13:51 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <8r37ju$o44$1@uranium.btinternet.com>
Source record: 178941

As the frequency is swept over the band, minimum SWR with
the meter located immediately at the transmitter always
corresponds to a resonance in the tuner+feeder+antenna
system. If it doesn't then suspect your measurements or the
computer program you are using.

Resonance means that at that frequency there is a purely
resistive load, R+j0, presented to the transmitter.

Only when the purely resistive load is 50 ohms will the SWR
be 1:1. Assuming, of course, you can trust your SWR meter.

Other values of SWR mean that the purely resistive load is
greater or smaller than 50 ohms, but there's no way of
determining from the SWR meter reading which of the two
alternatives applies.

Take your pick ! Fortunately it doesn't matter very much
with modern amateur transmitting equipment what it is -
provided the SWR is less than 1:5 which means the resistive
load on the transmitter is between 33 and 75 ohms.

Be thankful Japanese transmitting equipment manufacturers
allow for such wide variations in expected antenna
performance.

3874. Re: Inverted V

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-29 23:48:56 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <8r39na$h2$1@uranium.btinternet.com>
Source record: 178942

With an inverted V resonant dipole the feedpoint resistance
is more likely to be nearer to 50 ohms than a high
horizontal 1/2-wave dipole. The angle included in the V
actually reduces radiation and feedpoint resistance.

So you could deliberately deform your horizontal dipole into
a V just to provide a better match to your 50-ohm line.

DON'T DO IT !

The loss in height, the increase in ground-induced loss, the
reduction in radiation resistance, considerably outweigh any
slight improvement obtainable from a questionable better
match to the feedline.

If backyard space forces you to use an inverted V try to get
the apex as high as possible above ground or house. And
make the included angle between the two halves as large as
possible.

A resonant inverted V may be 2 or 3 percent shorter than a
resonant dipole due to an increase in capacitance to ground.
It depends on height above ground. When the whole antenna is
above 1/4-wave in height forget a change in length.

This is really a very small amount and whether using a V or
or horizontal dipole always allow for a teeny bit of
pruning.

Tom, W8JI wrote:
"---it acts just like the generator is sourcing through a resistance close to the load resistance with very little of that resistance making heat."

When you have two resistors in series, R1 & R2, the voltage across R2 is (R2 / R1+R2) times the total voltage across R1+R2. This is just the voltage times the fraction of total resistance represented by R2. It`s like the output voltage of a potentiometer or a voltage divider.

The gain formula for a Class A amplifier contains the same sort of fraction because the amplifier tube is a resistance also. It is a variable grid controlled resistor, RP, and is like R1 above. The load resistor, RL, is like R2 above.

The formula for the gain of a Class A amplifier is similar to the output voltage formula above. A tube has a geometry causing an amplification factor. Stage gain is more involved because it is output voltage over input voltage which depends on the voltage appearing across the load resistance and that voltage is reduced by the plate resistance of the tube in the way predicted by the ratio between two resistors as mentioned above.

Stage gain is equal to amplification factor times the load resistance, RL, divided by RL +RP.

The Class C amplifier works differently from the Class A amplifier because it is biased past cut-off and only conducts during less than half the cycle in short high amplitude pulses. The transistions between off and on and between on and off are designed to be quick to avoid power loss caused by simultaneous voltage across the tube and current through the tube, as occurs in the Class A amplifier.

Loss in the Class C amplifying device varies during the cycle from none while the device is switched off, to relatively small while the device is switched on because the switched on voltage drop of the tube or transistor is small even though the current is large.

When constant power output is being delivered by a Class C amplifier, its output is limited to some extent by the tube or transistor because the tube or transistor has a small resistance while conducting. The apparent resistance of the amplifier is higher because the amplifier is switched off most of the time. So, the apparent resistance has two components. One part is the resistance of the amplifying device(s) while switched on, and the other is the off time of the amplifier while no power is being lost.

Both of these effects have no direct connection with energy storage (reactance). An on/off switch stores no energy and the power loss in the plate or collector of an amplifier is instantaneous. So either of these inhibitions to energy flow would be "real". Both are resistances.

Maybe, the on/off switch is a lossless resistance (except for the switch`s imperfection). If this is so, I`ll tell Walt Maxwell and John Fakan that I finally "got it".

Best regards, Richard Harrison, KB5WZI

> 73, Cecil, W6RCA http://www.mindspring.com/~w6rca

Yeah, good question Cecil. The posts in response to my comments have been useful in helping me understand the dynamic resistance thing in rf amplifiers (thanks, Bill and others), but I still don't agree that it applies to electrical generators. (Well, I agree that dynamic resistance is a real effect, just not that it brings about a match of source and load.)

I do agree that the voltage adjustment brought about by the feedback loop makes it impossible to calculate the "real" source impedance of the generator by varying the load and measuring the results. But this skewing of apparent internal impedance has nothing to do with matching the machine to its load and everything to do with just simple voltage regulation.

Recall the quality value on power supplies given in percent regulation? Less was better. Back before electronic (feedback) regulation, you generally achieved better regulation just by using huskier components--bigger transformer, lower resistance chokes and so on. (Plus some complex factors in filter design too.) So you got better regulation mainly by lowering the source resistance. This didn't help efficiency a great deal (ohmic losses were reduced, of course) and it certainly didn't match the internal resistance of the power supply to the load resistance.

Now, modern power supplies (and generators) use feedback to control voltage regulation. This makes the source resistance look much smaller. So to summarize (and maybe clarify), I agree that feedback on a generator makes the source impedance look smaller when it is measured dynamically, but I don't agree that this is done to provide any kind of match or to increase efficiency.

And finally, getting back to Cecil's question--
>
> Unfortunately, multiplying that series impedance by the square of the
> current through it often does not yield the true dissipation inside the
> generator. Why not?

It's because that series impedance (meaning the one you measured dynamically with feedback "ON") isn't the actual impedance of the machine. Depending on how much gain you use in the feedback circuit (and whether you use an integral term), the value can be as low as you want it to be, all the way down to zero. Again, this argues against the notion that the feedback circuit is matching the source impedance to the load. The load surely isn't at or near zero ohms.

Roy,

As you assume, there won't in general be a single conductivity and permittivity that will imititate a stratified ground. However, the calculation with a stratified ground, for the case where all the wires are above ground, is not substantially harder than the original Sommerfeld calculation. I think the problem is that it is already difficult for hams to measure ground properties and measuring them accurately as a function of depth would be much harder.

As you probably know, Sommerfeld's method writes the fields of a small current segment in terms of an infinite set of cylindrical waves which, for the region below the current, are propagating outward and downward. (There are also some that are like those from total internal reflection that are exponentially damped rather than oscillating.) The propagation constants outward and downward, give the angle of incidence with the ground, and, breaking the waves into horizontally and vertically polarized components, the problem reduces to calculating the reflection coefficient of these waves from the ground. Once the reflection coefficient is calculated, the process is reversed and you build up the components of the fields from these reflected waves. The final results are the usual Sommerfeld integrals.

The reflection coefficients used by Sommerfeld were first derived by Fresnel around 1820, (that is well before Maxwell or even Faraday) and often are called the Fresnel formulas. However, their derivation from Maxwell's equations leads to equations that are the same form as the transmission line equations that we use to calculate the reflection from the junction of two pieces of coax. That is for air above and ground below, for each incident angle and polarization, you can show that solving Maxwell's equations is identical to solving for the reflection from the junction of two transmission lines, one with propagation constant and characteristic impedance representing the air, and the other representing the ground. The one representing the ground is lossy and taken to have infinite length, so any transmitted wave is

eventually dissipated.

Anyone who does the above calculation, will realize that a stratified ground with say N layers is equivalent to N different types and lengths of transmission connected together. Multiplying a few 2x2 matrices gives the reflection coefficient that a wave incident from the air "transmission line", and plugging this in to the Sommerfeld integrals gives the fields above the stratified ground. The Sommerfeld integrals for both source point and observation point in air will continue to have the nice property that they depend only on the radial distance and the sum of the vertical distances apart, so the 2-dimensional tabulation and interpolation used in NEC-2 will still work fine.

For any single angle of incidence, we can come up with a single conductivity and permittivity that will give the same reflection amplitude and phase, but in general, a single value won't reproduce the stratified case particularly if the stratification matches the downward component of the wave length in the ground so that you get something like a diffraction grating. For most situations the differences won't be so important. For example, for ground with high loss in the first layer, the differences won't matter so much since additional reflections from the lower strata will be damped out before they reach the surface.

I hope it won't, too, since I can't type all the little symbols
it takes to do electromagnetics justice. I'm glad to learn that
phasors and vectors can be treated the same way, it makes life
much easier. Now, how do I divide one three-dimensional vector
into another? This must be something new, because all my books
on the subject say it can't be done and my HP calculator sneers
at me when I try it, while dividing one phasor into another is
a cinch. Secondly, how can I take the cross product of (a + jb)
and (c + jd)? The books don't define this, either, and, needless
to say, the old HP48GX won't do it. If you've figured out how to
do these things you're a greater genius than Josiah Willard Gibbs,
and perhaps, who knows, even Hermann Grassman the eminent 19th
century mathematician who thought much of this stuff up.

Perfect component efficiency, but maybe not so good system efficiency.
Since you are on the east coast, the electricity you used was probably
generated with heat (from burning coal or oil, or maybe fissioning uranium).
The second law of thermodynamics limits the efficiency of the process of
turning heat into electricity to probably 60-something percent, with the
remaining heat being wasted out the cooling tower at the generating
station. So only 60% of the heat required to make the energy you used
ended up in your bathroom.

Hi

I have been reading this newsgroup for a year and I was just wondering if anyone had any experience with helical antennas on HF. I like to experiment and was considering building one for ten or 15 meters. Does anyone have any hints or know of anyone who has been succesful with idea?

Thanks and 73,
Matt

Therefore, our power/SWR meters are all wrong? There's absolutely no difference in the signals in the coax in the following two examples. The power in the coax equals Pg. The voltage in the coax is Vg. The current in the coax is Ig. The phase angle between the voltage and current in the coax is zero. The ratio of Vg to Ig is 50 ohms. There is no measurable difference and there are no reflections on the coax after steady state has been reached. All reflections on the coax have been neutralized by the interference pattern at the Z0-match and the generator sees 51.5 ohms.

100w--->---51.5 ohm coax--->---x--51.5 ohm load

100w--->---51.5 ohm coax--->---x-----1/2WL 300 ohm line----51.5 ohm load

Hey, a perpetual motion machine. Use two phase-locked IC-706s to
each put 100 watts into a transmission line with the angle between V1
and V2 equal to zero and get 400 watts out - no SGC-500 required.
Better get a patent on that thing, Steve.

> discussion of what's happening at the ZO match and how the driving an
> re-reflected waves combine to be 200 watts.

Don't know exactly how they combine, Steve, but the boundary conditions
are 100% known and the results are 100% known. With a 50 ohm power meter
and two 300 ohm power meters, you can read the generated power = 100w,
forward power = 200w, and reflected power = 100w. The Z0-match doesn't
get hot so we know that the conservation of energy principle applies.
Therefore the generated energy combines with the reflected energy to
yield the forward energy.

Pg >>>> P+ >>>>
100w-->--51.5 ohm coax---x---1/2WL 300 ohm line---51.5 ohm load
<<<< P-

Pg is measured at 100w. P+ is measured at 200w. P- is measured at 100w.
Vg/Ig = 51.5, V+/I+ = 300, V-/I- = 300, Vg*Ig=100, V+*I+=200, V-*I-=100
That's six equations and six unknowns, Steve. A high school algebra
student can solve for the results.

Hello Dennis-

It's even worse than that. Actually, the efficiency of a modern steam turbine electric power plant is about 30%. And they do push the theoretical limit pretty hard.

BTW--Ed didn't say the bathroom heater is electric. If it's gas, he may have that 100% "system" efficiency.

When transfering power from a 50 ohm line to a 300 ohm line, the voltage must
increase and the current MUST DECREASE in order to honor the conservation of
energy principle. Therefore, the currents have to be out of phase to add up
to a lesser value. So your statement is prima facie false.

I haven't read the CQ articles but I know the phasors don't act at a virtual short exactly the way they act at a dead short. But we know all about the steady state signals so we can make the "theory" fit the known circumstances. Maybe we can say it is virtually a short. :-) Maybe that's what Walt meant in the first place.

Saying Walt was "wrong" is like saying Newton was "wrong". What Walt says works in the same way that what Newton said works. Even if the concept of a "virtual short" does not stand up under a rigorous mathematical treatment, it is still a useful concept. A novice is much more likely to understand the concept of steady-state re-reflected power than to understand the infinite series of interference patterns that underlies the concept.

ARRL Editorial came be blamed for many things. 'Blackisting' of Harvard Ph.D.
Walt Maxwell is not one of them.

I have always found Dr. Maxwell's materials on transmission lines and baluns
extremely valuable and accurate.

I have a copy of 'Reflections' and am glad the ARRL published the book.

I am not so naive as to assume a business decision--right or wrong--in any way
reflected (so to speak) on the author.

Read Walt's stuff at any opportunity--it speaks with the truth of things.

Hi Alex--

Log periodic arrays work well when you need basically the same performance over a wide frequency range, such as for your TV. They have specific geometric attributes that makes this possible.

Although LP's may superficially LOOK like yagis, they are not parasitic and are relatively narrow in bandwidth.

So you need an LP.

If you do a search for TV log peridoic I am sure you will find adequate instructions on building your own, although truthfully they are cheaper to buy off the shelf--at least in the States.

It's really hard to say but I would expect it to be vertically polarized
with most of the gain coming from the narrow horizontal beamwidth.

> 2. I have found a replacement antenna designed for exactly the same kind of
> service that is 39 inches wide...it is a screened reflector dish with stated

> the high directivity of the larger antenna)

At first blush, you indeed would expect the signal to increase by a
minimum of 9 dB and for the multipath, on the average, to be decreased
as well. I doubt active noise sources are a problem but that could
change in a couple of years. Should be a win-win as long as you can
maintain the antenna pointed correctly.

One minor point in favor of the flat plate antenna is that it probably maintains it's low sidelobes for horizontal polarization better than the dish. Look carefully at the pattern for a cross polarized parabolic reflector. At large angles off boresight, the response to the 'wrong' polarization is considerably larger than you might expect. This can have the effect of reduced multipath rejection and is in fact can be a significant weakness in certain military systems.

I seriously doubt the cross polarization response will significantly negate any of the improvements expected but is something to consider.

> The antenna can be seen at :
> http://www.hyperlink.cc/antenna2400.htm

The link doesn't seem to exist?

>
> 3. What is the attenuation per 100' of LMR 400 coax at 2.4 gig?

Don't know but you should be able to find it on the web easily enough.

> dBm.
> With the new antenna, I should expect a signal level of -73 dBm...which
> would be quite an improvement and the noise floor might drop too?

It might, but my expectation is that at the end of the feedline, your noise level will be determined by receiver noise figure and not external interference. What is the system bandwidth? Thermal noise is -114 dBm in a 1 MHz bandwidth.

> Why am I considering this? Well....the software (as well as the installer)
> says I have a "marginal" signal level. I have about 13 dB S/N and they would
> like at least 16 dB and preferably 20 dB.

Sounds reasonable. 13 dB is right on the knee of the bit error rate (BER) vs SNR for FSK or PSK systems operating without (or before) forward error correction (FEC). 17 dB is kind of a nominal number and another couple of dB for fading (on an assumed _non_ fading channel) and correlated multipath is a good idea.

Hi Tom:

Thank you for asking for an explanation. I appreciate it very much. I will address your comments and hopefully those of Cecil and others as well.

First, Cecil is correct that power is a scalar quantity but it is important to understand that total power is determined from the addition of complex voltage phasors and complex current phasors, not from the direct addition of the scalar quantity of power.

In all transmission line systems (assuming that ZO is purely resistive) the forward traveling power in the transmission can be found simply as follows:

Pforward = |Vforward| * |Iforward|

OR

Pforward = |Vforward|^2 / ZO

OR

Pforward = |Iforward|^2 * ZO

Let's look at it from the perspective of voltage. Let's assume that the transmitter delivers a forward voltage to the 300 ohm line having a magnitude equal to 173.2 volts. This equates to a forward traveling power of 100 watts. Here's the first problem, knowing only the power, we have no idea as to the what the phase of the voltage is. It could be 0 degrees, 90 degrees, 180 degrees, etc.

Now, lets assume that the voltage re-reflection at the match point has a magnitude of 173.2 volts as well. This equates to a re-reflected power of 100 watts. Again, we have no idea as to what the phase of the voltage is.

Now we need to determine the total forward traveling power in the transmission line. We know that the total forward traveling wave is equal to the sum of the transmitter wave plus the re-reflected wave. Looking at power, most people immediately assume that 100 watts plus 100 watts is equal to 200 watts.

The addition of the transmitter wave and the re-reflected wave occurs as follows:

Vtotal = Vtransmitter + Vre-reflected AND Itotal = Itransmitter + Ire-reflected.

The important point is that all we know from the system power are the magnitudes of the voltage not the phase. As a result, we cannot correctly add 173.2 volts + 173.2 volts as vectors. I'll use the "@" symbol to represent phase.

IE. 173.2 @ 0 + 173.2 @ 0 = 346.4 @ 0 volts for which the power is equal to 400 watts.

173.2 @ 0 + 173.2 @ 90 = 244.94 @ 45 volts for which the power is equal to 200 watts

173.2 @ 0 + 173.2 @ 180 = 0 volts for which the power is equal to 0 watts.

Based on this fact, we see that 100 watts in phase with 100 watts cannot equal 200 watts. In the case of the example presented by Cecil, we know that we have 200 watts of forward power. So, if the total forward power is 200 watts, what's my explanation of what's really happening?? What's happening in Cecil's example is that the transmitter does not deliver 100 watts of power to the 300 ohm line AND the re-reflected power is not 100 watts. I'll discuss this in another post.

As for the conservation of energy, it only requires one thing: that the total power dissipated in the transmission line system be equal to the total power delivered to the system by the transmitter.

When examining the wave reflections, we should be able to maintain the correct relationships between adding voltage and determining total power.

The only parameters which really matter are height and the vee angle. You'd be
better off if the angle was 120 degrees or more than with 90 degrees. Use a 1:1
choke balun at the feedpoint. With the short coax run at 14Mhz tweaking a few
inches here and there to minimize the swr is a waste of time as far as losses
and effectiveness are concerned. Any swr below 2:1 will work just ducky. If you
just gotta have a flat swr do it with a tuner. Which you should do anyway in
order to reduce the amount of out-of-band RF that gets fed into your receiver
front end.

> be out of phase, keeping the 100+100=200 math consistentent.

In any transmission line system, the ratio of forward voltage and forward current always obeys the following law:

Vforward / Iforward = ZO

If you have two forward traveling waves in the transmission line where both have voltages that are in-phase, then the current must be in phase as well. If the current waves of each were 180 degrees out of phase, then the voltages would be 180 degrees out of phase as well.

The total forward voltage in a transmission line = Vforward1 + Vforward2

The total forward current in a transmission line = Iforward1 + Iforward2

Anyway, if the currents were out of phase and traveling in the same direction, they would cancel one another and the total forward current would be zero.

>Does anybody know of the QST article, year and month, where they compared the
>losses and matching ranges of various commercial antenna tuners? Thanks.

March 1997 was one of them, comparing the high-end tuners.

It can be downloaded from (sorry, this one is on the members-only site):

http://www.arrl.org/members-only/prodrev/pdf/pr9703.pdf

I will add that Tom Rauch and I have been having some discussions about the accuracy of the method used to measure the losses. It is yet tbd, but there is a possibility that the measurement uncertainty may be high toward the high end of the range.

There are a few unreviewed tuners, so QST will probably do another. For that Review, the ARRL Lab will use three different test methods (the original, plus two others) and evaluate the results. The most accurate of them will be published. If this evaluation shows any significant deviation from the results using the original test method, I am going to ask the editor if I can do a sidebar, explaining the differences. The original method used was developed from a testing technique developed by Witt and published in the April and May 1995 QST. The articles are available at:

http://www.arrl.org/tis/info/tuner.html

As always, discussion and inpt are welcome. :-)

Tom:

One important point I forgot to mention.

There is a formula for adding two forward traveling powers in a transmission
line:

Ptotal = P1 + P2 + 2 sqrt(P1) sqrt(P2) cos(theta)

where theta is the phase angle difference between the voltages V2 and V1.

'fair use' and 'derivative work'. use of published material is normally legal as long as it is properly attributed (see the "mi2 loop.txt" file in the same directory as the eznec model), and is not a substantial part of the original work. didn't i remember that roy transcribed this from a published article? as such it was surely just a single figure or two in that article and as such would probably be only a small part of the original work. and if the original wires table wasn't published at all as it sounds then there may even be doubt that it could have been copied in the first place. and being 'recognizable' doesn't necessarily prove infringement. the use of the main melody of very recognizable songs is legal for parodies with new lyrics. speaches and recognizable writings are frequently, and legally, modified and published as parodies. copying and quoting technical work of others then improving or adding to it is a standard practice and does not require prior permission unless using a substantial part of the orginal work.

look at this from a more generic point of view with this situation:
1. person-a publishes an article with pictures, graphs, and word descriptions of a design for item-x. they make certain claims that item-x works a particular way. they do not publish their design files or specific parts of them that would let someone else duplicate their work.
2. person-b reads the article and says 'i can do better'. taking the description of item-x and looking at the pictures they reverse engineer item-x and create their own model of how it works in a different (or even the same) modelling program. from that derived model they learn how item-x performs and find that it has some shortcomings and can be done just as well or better a slightly different way.

first, if this were scientific work i would expect person-b to publish their work citing person-a's work and showing how it was wrong or how it could be improved. this is done all the time in technical journals.

second, if this were a comercial product i would expect person-b to file a patent application with specific improvements on the original design... and if granted and if person-a wanted to use those changes person-a would have to buy them from person-b.

so fire up that patent process roy, you may have something here if fracky is so keen to squash it!

'fair use' and 'derivative work'. use of published material is normally legal as long as it is properly attributed (see the "mi2 loop.txt" file in the same directory as the eznec model), and is not a substantial part of the original work. didn't i remember that roy transcribed this from a published article? as such it was surely just a single figure or two in that article and as such would probably be only a small part of the original work. and if the original wires table wasn't published at all as it sounds then there may even be doubt that it could have been copied in the first place. and being 'recognizable' doesn't necessarily prove infringement. the use of the main melody of very recognizable songs is legal for parodies with new lyrics. speaches and recognizable writings are frequently, and legally, modified and published as parodies. copying and quoting technical work of others then improving or adding to it is a standard practice and does not require prior permission unless using a substantial part of the orginal work.

Here's some numbers for the example used in the original QEX article.
The transformer is a section of 75-ohm line joining 225-ohm line at the
source and 25-ohm line at the load. The source is 1 volt. Looking at the
right side of the 225-75 junction, the wave components (at steady state)
with the notation X|Y used for magnitude|phase are

partially transmitted toward the load
E = .5000|0
I = .006666|0
power = .003333

partially re-reflected toward the load
E = .1666|0
I = .002222|0
power = .00037

net toward load
E = .6666|0
I = .008888|0
power = .005925

On the 75-ohm section, the impedance is .6666/.008888 = 75. which
exactly tracks the characteristic impedance of the line. The power on
both the 225-ohm section and on the 25-ohm section is .00444, so all the
power generated by the source is transferred to the load. The power on
the 75-ohm section is greater than on either of the other sections.

Notice that the net power flowing toward the load on the 75-ohm section
is not the sum of the individual power flows. And please, for all the
physicists out there, let's not get into whether or not power flows -

that's a topic for another thread. 73,
Bill N3WK

Hmmm, This is a familiar sieve. This repository must hold the secrets to fractals to be so selective. Undoubtedly this org fosters the same perception of arrogance and through that is suffering a declining interest from the greater population of Hams.

Correlatable as far as I can tell. Causal? Seems so from the tenor of grief expressed by so many posters here for any of these organizations that hide their knowledge (errors?).

For groups desiring to be representative, it is a sad irony that they with-hold what some might find interesting. I bet $money$ underlies this motive.

All such organizations should observe the model of
http://www.qsl.net
to find Free and open publication and access to any data. qsl.net has $money$ issues too, but doesn't need to charge a 5 drink minimum for a fractal table dance (which is to say qsl.net is easily distinguishable from a chip-joint). How do they do it? Through subscription and "voluntary" contributions. Volunteerism - this seems to be a lost practice for some while an art for others.

Thanks for the clarification.

I didn't answer the question because I don't know what "effective depth" is, but I'm glad you weren't so inhibited. And since neither of us knows quite what it is, you're right -- 1/2 is certainly as good as 0.69. Spot on, as always.

Hi Cecil,

The statement above is called hedging your bet.

The appeal to this strained logic of Walt's is that it is useful as a teaching aide. Unfortunately, the student must first understand what is supposedly being demonstrated, to understand what is being demonstrated. Walt's work is self-referential, that is, his chain of proofs presume the thesis is true to prove the thesis is true. Once accomplished, critics are dismissed if they attempt to presume the thesis is false - it has already been proven true.

Your allowing that
>a "virtual short" does not stand up under a rigorous
>mathematical treatment
is in marked contrast to Walt's rigorous mathematical treatment. Hence my assertion above of this logic being circular.

If this notion of virtual shorts and opens is simply a means to convey a concept, then Walt can state as much, as simply - and without the math. The student can then listen and observe - while understanding these are an artifice, clever but not necessarily correct. The student, then, when asking a question, can expect a specific and correct response - not an elaboration of that fiction which, when questions are pursued, becomes even more baroque.

I don't know whether Walt is right or wrong, because I haven't
been able to get his book. I do believe, however, that before
any guru, such as Gary, condemns Walt as wrong, that guru should
make the intellectual effort necessary to thoroughly understand
the subject, himself. People may balk at having to think about
an infinite number of reflections, but the point is that they
don't have to. Newton and others made that possible in the
17th and 18th centuries. As for Walt's use of metaphor in order to
explain the energy movement in transmission lines, there's nothing
wrong with that as long as the metaphor isn't too strained. Popular
science writers do it all the time. It may be too elementary for
a polymath such as Gary, but for ordinary people who don't have
time to learn the sometimes mind-boggling physics and its attendant
mathematics it works very well.

The fact that you use a differential operator on the ratio
of voltage to current means that the ratio isn't a constant as it is in
say a lump of carbon - O.K., as long as the carbon doesn't get
too hot. This is liable to cause some confusion in the minds of
people who are looking for "the resistance" of the plate in question.
Power amplifiers don't behave the same way passive devices do, and
attempts to linearize them in order to understand them using
circuit theory may eventually cause more confusion than understanding.

Yes, and I have killfiled this bozo and his derivatives but the thread keeps changing. It would be very helpful if everyone would decide on a word that could be put in the header to signify that the post is pertaining to this fool so that it would be easy to filter out. I have been reading this group for about three years. I have seen this twerp, excuse me, twerp PHD, go from a relatively minor annoyance to a major PIA. I have also noticed the absence of people who (whom?) in the past I had learned a great deal from. They have undoubtedly become tired of wading through the BS to find anything useful, as have I. I now only occasionally red this group where in the past it was the first on the list. It is a shame to see it this way as the information gleaned from this group is available nowhere else.

Hi Cecil,

Are you thinking of .co.uk perhaps? I think that was pretty much the standard for many years, along with edu.uk and gov.uk etc. I don't recall seeing .gb at any time but I'm certainly not an internet freak so don't place too much reliance on that!
I recently did a search on my callsign and was offered the choice of domain names .com .net (and a couple of others I don't recall) from a US source. Seemed good to me so I paid up and steered the email back to my existing isp and here we are. Nice simple email address which I can even remember myself.....

I checked your site and have also downloaded some info from Hustler and several other manufacturers. Predictably the commercial data adds to the dilemma as it becomes necessary to cut out the 'sales-speak' before trying to assess what is on offer. Your shoot-out is at least a real world assessment rather than computer predictions or carefully chosen anechoic chamber measurements.

The responses so far have confirmed what we all know inasmuch as small inconspicuous antennas are never going to be efficient compared to putting lots of metal in the air. I was just hoping that someone had perhaps followed this path before and arrived at a 'best solution'. I'm quite willing to let someone else do some of the legwork and from following the newsgroup for a few weeks it is obvious that there is a wealth of prior legwork here.

Thanks for your interest and 73, John G8OZH

I know of several Magazine stores here locally that carry QST.
Also the local community college is a good place to browse for free as well which is what I did
before subscribing(joining ARRL) in 1986 to receive their magazine.
Incidentally I was not a ham at the time I joined. I was just interested in getting
their magazine. You can get on CD ROM all the magazines that I have currently received boxed away plus
another 16 years at a still cheaper price than I paid for subscribing for 14 years. That's 25 years
worth of QST reading. As for the declining interest of ham radio
it is common knowledge that most hams do not subscribe to Ham related magazines.Wayne Green of 73' magazine comments on this all the time. I can understand.
Currently I receive over 1/2 a dozen radio related magazines monthly. It keeps one busy.
That's why I still prefer the ability to carry the magazine with me and read as time permits.
In the years since I first joined and started receiving QST, it has changed dramatically.
You no longer see the multi-month construction projects but see more in a nutshell articles.
Sometimes the reviews are not unbiased either.
For instance an ICOM R-75 receiver ,that I am interested in ,the QST review made no note at all that the
synchronous detection was a weak point in the radio if not functional at all.
This has been documented by many others.
But the QST reviewer missed it.
So crosscheck your reviews. They may have missed something.

In a previous post just yesterday I discussed this. It is true that there are some nonlinearities in the plate "resistance", whose value is dV/dI. But a tuned filter, or even a low pass filter, smooths out these variations so that the filtered output has an "average" value of dynamic resistance at the fundamental RF frequency. In a high quality linear amplifier these variations are not very large.

The problem is that as the level of modulation changes this average value also changes. I believe that a two-tone output signal with low intermodulation distortion is the best signal for evaluating the "large signal" dynamic resistance over the full range of the *modulation* signal.

If you look at the constant-current curves of a tube you can see the nonlinearities. The plate resistance variations contribute to the nonlinearities.

Hi Tom,
Yes, they're complex numbers, but they can be represented as vectors.
The usual vector operations like addition and dot product apply. For
instance, to add two phasors in cartesian form (x+jy), add their
separate components. The cosine of the angle between V and I is the
power factor. And so on. I hope this won't diverge into
electromagnetics. 73,
Bill N3WK

Floyd--

Once a month I post this invitation to folks on this NG. Its quite alright with me if it doesn't suit your needs. But to brand this and my other posts as "rubbish" tells others that they shouldn't have the right to decide for themselves.

Could you kindly tell us what experience--negative or positive--you had on these groups which led to your characetrization as "rubbish".

Or.,do you not mean to say, instead, that it just isn't something that has a personal interest--to you?

Source record: 178914

Roy asked -

> What does the output of your rig do when it's confronted
with 1.8:1 SWR?

==========

I have an Icom 735.

I tested it at 1.9 MHz in FM mode using a small number of resistive loads of known values, doing nothing except changing the load resistance and determining the load power by measuring the RF voltage across it. I don't trust SWR meters.

Load ohms SWR Rel Power

17 3 70 %
34 1.5 91 %
50 1.0 100 %
97 1.9 89 %
113 2.3 78 %

Draw a best-fit parabola through these points and when the SWR is 1.8 the two relative power levels are 84 % and 92 % which I admit are higher than I expected.

Whether any SSB distortion due to PA non-linearity occurs at these relatively high SWR's I don't know. Doesn't matter on CW and FM of course.

On closer inspection of the ALC circuitry I see that the SWR bridge Forward voltage takes control until the Reflected voltage exceeds some critical value at which point the reflected voltage is used to throttle back the PA drive.

Excessive PA current is not prevented by any RF measurement but simply by detecting the DC collector current. When the DC current exceeds some critical value a control signal is fed into the ALC line.

I am not familiar with your Bird wattmeter. Does it measure load power directly in some manner or by indicating the difference between forward and reflected power levels ? Does it first have to be calibrated or "set" in conjunction with a 50-ohm standard load ?

Reg.

Excuse me;

First, I have no reason personally to even think of Roy Lewallen or his company. So what you state is not only not possible, but not relevant.

Second, this public notice was posted--appropriately--on the same public NG as Roy Lewallen's public announcement about his (unauthorized) publication and distribution of the MI2 file.

Fractal Antenna Systems, Inc., which is the copyright holder, see no reason at present to pursue a lawsuit. That will change depending on what actions are taken before December 15, 2000 by Mr. Lewallen.

But, so you know, Mr. Lewallen has privately corresponded in words that indicate that ANY public disclosure of Mr. Lewallan's unuathorized publication and distribution will be interpreted as a basis for actions against Fractal Antenna Systems, Inc.

Copyright holders commonly, indeed must, inform the public when unuathorized use of copyright material is occurring in a very public and accessible medium such as the internet. If FAS did NOT disclosed this unauthorized use (after Mr. Lewallen refused to accept the situation and indicated he would not remove it) then it would be interpreted as a 'go ahead' for piracy.

I hope this helps.

Nathan Cohen, Ph.D.
CTO
Fractal Antenna Systems, Inc.

Barry--

You are being demeaning.

What is the intent of your post, given that it couldn't possibly be true? For example: over 450 different folks subscribe yo the reflectors so listed.

Are you callung them "horse's asses"--as you say-- for doing so?

No, I'm definitely not saying that. That would yield about 13% effiiciency,
which I wouldn't call "maximum" by any means. I'd think a big modern
generator probably does aound 99%.

>
> 73 Tom

I don't think so. It's true that a typical power plant generator will have an automatic feedback system controlling the field current. But this isn't used to optimize efficiency. It's to regulate terminal voltage. (Actually, when the generator is alone supplying a load, the field adjustment controls the voltage, and when the generator is feeding a grid (many generators and loads), the field adjustment controls the VAR loading).

The generator is going to be fairly efficient whether half loaded or fully loaded, although efficiency will probably be best at full load, due to certain fixed losses. You could put the excitation control in "manual" and run the field current (and therefore output voltage) up and down some and not affect efficiency a heck of a lot. Of course, some of loads may not be too crazy about those voltage excursions.

I'm confused about this concept of a non-dissipative, dynamic type of resistance. It really confuses me in postings on rf amplifiers--maybe I can get a handle on it with generators.

I'll take a shot at it myself. If we have a black box (voltage source and series impedance assumed), we can measure its impedance by loading it to a certain current draw and measuring the terminal voltage, then changing the current drawn and measuring the voltage again. This should allow a fairly easly calculation of the series impedance in that Thevenin box.
Now, if the thing in the box has a feedback control system and the voltage source isn't fixed but variable ... the feedback control could crank the voltage back up to its former value as current is increased. Because we assumed a fixed ideal voltage source and series impedance, we now calculate a much lower value of apparent internal resistance. (Zero, if the voltage doesn't droop at all with increased current.) Is this shift in calculated resistance the non-dissipative resistance we're taking about? If it is, I still don't see how it's going to affect efficiency.

Ah, antennas, great big generators, and conjugate matches ...

73 and good night--

Nick, WA5BDU

Yes, it is a dynamic, lossless resistance. The output resistance of a tube or transistor PA is actually an internal negative feedback effect. That is, the variations of *plate voltage* produce variations of *plate current* because of an inherent characteristic of the vacuum tube design, called its plate resistance. This plate resistance is equivalent to a gain reduction. That is, the voltage gain of the tube with plate resistance is *less* than the voltage gain of the tube without the plate resistance "effect". Plate resistance itself does not dissipate power. It is not a physical entity. For example, it does not get hot and it is not a source of thermal noise, like an ordinary resistor.

If a tube without the plate resistance effect is replaced with an almost identical tube that does have a plate resistance effect, that effect can be nullified by increasing the grid drive a little. This restores the tube to its previous voltage gain and its previous power output and efficiency. This verifies that plate resistance is a lossless "resistance" (dV/dI).

Dear Roy, try not to be so nit picking. Or have I misjudged you ? ;o)

Somebody asked very vaguely what was an effective depth of the soil from an antenna's point of view. So in the absence of any suggestions from guru's like yourself, indeed avoidance, I offered a practical value of half of the skin depth.

Why didn't you offer to the enquirer an effective depth of 0.69 times soil skin depth ? I wouldn't have quibbled about it.

If you knew a litle more about the subject than the number 0.69 you would know that, assuming a uniform current distribution, the resistance of a surface slab of resistive material of thickness equal to the skin depth, with nothing at any greater depth, is the same as the actual resistance of an infinite depth of the material with an exponential current distribution versus depth.

With a uniform distribution of current in a slab of thickness equal to the skin depth it seems resonable to assume the effective depth to be half of the skin depth. This applies equally to soil inductance and mutual inductance estimates.

To illustrate the point a little further, on the subject of the characteristic impedance of coaxial transmission lines, where the radial dimensions of the coaxial conductors control Zo, when calculating inductance of the outer conductor it is usual to increase the effective radius by 1/2 of the skin depth. Similarly, the radius of the inner conductor is reduced by the same amount. This allowance for skin thickness has a significant effect on the impedance of lines at the lower radio frequencies.

As for how else 'effective soil depth' could be useful you had better ask the person who asked for an estimate of it.

It may be of some small interest that in some of my antenna programs I have used the concept of adding 1/2 soil skin depth to antenna height. This only affects matters when an antenna is very low or actually lying on the ground perhaps in the form of a radial ground wire. Even then it is not of vital consequence.

What's a quarter of an S-unit, specially yours, more or less
? ;o)

Yes, sometimes called phasors with a magnitude and an angle. However, at a Z0-match point all phasors are either in phase or 180 degrees out of phase. Thus, ordinary arithmetic works just fine *at a Z0-match point*. Phasors with a zero degree angle get a plus sign and phasors with a 180 degree angle get a minus sign.

Unfortunately, multiplying that series impedance by the square of the
current through it often does not yield the true dissipation inside the
generator. Why not?

The effective depth of the ground can be taken as half the
skin depth of the soil under the antenna. It depends on soil
conductivity (or resistivity), permittivity and on
frequency.

Its not of great consequence. If you don't know the soil
conductivity in your back yard just run some of it through
your fingers and make a guess.

To find skin HF depth of the soil use program SOILSKIN.
Download from my website in a few seconds. Not zipped up.
One small file only. Run immediately.

To All Readers:

It has come to my attention that Roy Lewallen, W7EL, has posted an unauthorized copyrighted file on his

http://www.eznec.com

web site.

The file is of a fractal antenna, commonly dubbed 'MI2' . The copyright holder of this material is Fractal Antenna Systems, Inc., which has not been ask for , nor has granted, publication and distribution of this file by Mr. Lewallen.

The file was transcribed by Steven Best and thus is a derivative work of the aforementioned copyright material, in which the copyrighted material is at least substantially recognizable in Best's rendition.

It has been initially assumed that Mr. Lewallen was not aware of the copyright infringement, however in private correspondence he has chosen to deny that such copyright protection exists.

Mr. Lewallen is being formally sent a letter requesting that he cease and desist the further distribution of this copyright material and will have until December 15, 2000 to comply. Failure to do so will lead to suit against Roy Lewallen d/b/a Lewallen consulting/EZNEC.

Those who have downloaded this file are so advised that this is copyrighted material with an intended controlled distribution; it is not in the public domain; its web-based distribution does not constitute 'fair use'.

Copies of the file are available--under held copyright--by request, to those members of the fractal antenna reflector:

fractalantenna-subscribe@egroups.com

In a few weeks, it will also be available as a conditional(licensed)download from the web site

http://www.fractenna.com

Readers are advised not to break copyright law by downloading said file from the EZNEC web site.

Thank you for your help and understanding.

Sincerely,

Nathan Cohen, Ph.D.

Hi Wayne,

The height and apex angle you plan on are very nearly the same as my
Inverted V fractal design found at:
http://www.seanet.com/~rwclark/fractal/InVfracV/index.htm

This is not a 20M antenna though, but is tunable. The SWR chart that
is presented for this band (and all the others not in the 10M band) is
(are) due to the inclusion of either an inductor or capacitor at the
feedpoint, so don't let that mislead you into thinking it already
matches to 50 Ohms.

I don't have a comparison design to demonstrate how much you stand to
gain (or lose), and if it seems too complex - fractals being what they
are - you may opt to pass this by. It is "experimental."

The rationale (which "should" be supportable through modeling) is that
by drawing up the ends of the V, you should not suffer as much loss as

for the ordinary V that you might otherwise construct. I will admit this is a boon in name only, because at these scales there is very little you can do to boost gain, and most effort is trying to escape the death grip of ground.

Another fractal antenna, tuned to 20M, is found in either the k2 or the Flying H located at:
http://www.qsl.net/kb7qhc/antenna/fractal/n1ir/k2/index.htm
These two illustrate how by pouring your power into ground, you can improve your gain at one angle, 10 degrees. This is an optimization available to low, low antennas only (thank your stars you aren't painted into this corner - some folks are) as compared to equally crippled designs. As the two designs differ by only 0.5 dB, you may wish to consider the Flying H as being vastly simpler to construct. I will warn you however that these ground huggers exhibit wild variations in SWR with small changes in elevation (a 3 inch change in elevation is enough to peg your SWR meter). It makes no sense to operate these any further from earth, or any closer - there are too many better options. And improving the ground condition only makes operation worse. Oh well, we could classify these as extremely experimental (painful).

Hi Cecil,

Ha! So much for the first definition then. They could have been
thinking of sugar plum fairies when they wrote about dissipation:
"dissipation - loss of electric energy as elfin creatures frolicking
in the valley."

Pretty poor dictionary, doesn't even understand english.

Hi Bill,

As an electronics instructor in the Navy, I had to keep up with any
number of teaching and learning aids. I know several for the resistor
color code that I won't repeat here. I could in front of 30 sailors
and none would blush, plus it kept them from falling asleep (or
tossing me overboard).

Bravo - that's exactly what I did a long time ago. It certainly cleans up a
lot of the mess. I also found the kill file handy for those who post E-Bay
FA stuff as FS, along with posters selling CB stuff, dealer spam, etc.

If I have time I'll go thru your numbers, but the original question was
does 100 watts + 100 watts equal 200 watts. If there are two sets of
waves (take the 2 backward traveling and the 2 forward traveling),
you're equating (E1+E2)*(I1+I2) to E1*I1 + E2*I2. Voltages combine
vectorially, currents combine vectorially, but powers (which are dot
products of voltage and current) don't combine.

Rick, take a look in the latest Radio Shack catalog at their industrial radios. They are pushing a line that have coverages starting at 146 MHz and 450 Mhz or so. Not one word in the text re amateur radio bands, but they do stress that an FCC business radio license is required.

Hi Rick,
I do it all the time, it is fun working 20-10 meters right from the beach getting the top hat stabilized was a bear at first especially with a good wind blowing from the east on the south shore of Long Island.

I wonder how one can claim something publicly when they refuse to publish their so called version and then claim some form of infringements I wonder if his version meets the 27.564 m and an aperture size of 2.8 m (X) by 2.662 m (Y), I guess that it must be something really funny hiding under that kimono?
This behavior is truly bizarre even from that bunch of looping characters.

That's a good idea. I'd like to learn something about fractal UHF antennas. There's a "serpentine" decal antenna on the market for 440 Mhz, and I'd like to find out if there is any performance difference with a "fractal" one.
